A PRACTICAL MANUAL OF DISEASES OF THE CHEST

by MAURICE DAVIDSON, M.A., M.D., F.R.C.P.

Physician to the Brompton Hospital for Consumption and Diseases of the Chest (sometime Dean of the Brompton Hospital Medical School); Associate Physician to the Royal Cancer Hospital; Consulting Physician to the Miller General Hospital for South-East London; Consulting Physician to the Western Ophthalmic Hospital; Hon. Consulting Physician to the Papworth Village Settlement, Cambridge

THIRD EDITION 686 pages 281 illustrations 50s. net

OXFORD UNIVERSITY PRESS

Brand's Essence
(of Meat)

. . . has been recommended by doctors for over 100 years. It contains 10% of soluble meat protein, is free from fat and carbohydrate, and has a low salt-content.

Because it is rapidly absorbed, owing to the perfect state of solution of the protein, it makes no demands on the digestive system and can be given in cases of acute digestive disorder. Brand's Essence is unrivalled as an aid to convalescence after serious illness. From chemists, 3/- a jar.

NOVOCAIN
BRAND ETHOCAIN HYDROCHLORIDE

THE ORIGINAL PREPARATION
English Trade Mark No. 276477 (1905)

THE SAFEST AND MOST RELIABLE LOCAL ANÆSTHETIC

Does not contain Cocaine, and does no me under the Dangerous Drugs Act

Supplied in Tablets of various sizes. Powders, etc. Ampoules of Sterilized Powder and Solution. 1 oz. and 2 oz. Bottles, Rubber Capped

Prices have been maintained at pre-war levels

CALGITEX
ALGINATE GAUZE
ALGINATE WOOL

The ideal dressings for all burns and wounds

In the treatment of burns and wounds it is essential for the dressing to act as a barrier against reinfection. When treating infected burns and wounds it is essential to incorporate bacteriostatic or bactericidal substances in the dressing. It has been stated both conclusively and authoritatively that the danger period is during the "Change of Dressing".* CALGITEX ALGINATE GAUZE OR WOOL fulfils all the requirements of the ideal dressing. By being SOLUBLE in physiologically tolerated Alkaline media, they permit the change of dressing to take place without exposure of the raw surface to the potentially microbe-laden atmosphere. They provide the ideal dressing for both CLEAN and INFECTED accidental burns and wounds, also for OPERATION WOUNDS in all branches of Surgery.

The following developments are now available:—

FOR EXTERNAL USE

CALGITEX GAUZE in pieces 1 yd. x 15″
CALGITEX RIBBON GAUZE
in Packets containing 5 pieces (1 yd. x 1″)
CALGITEX WOOL
in Hospital size packets (containing approx. 3 ozs.)

FOR INTERNAL USE

CALGITEX GAUZE (Standard or Fast)
Packed in cartons containing 4 pieces (approx. size 9″ x 15″)
CALGITEX RIBBON GAUZE (Standard or Fast) Packed in cartons containing 5 pieces (approx. length 1 yd)
CALGITEX WOOL (Standard or Fast)
Hospital Size Pack (approx. weight 3 oz.)
Medium Size ½ oz. Small Size ¼ oz.

CALGITEX SOLUTIONS
16 oz. bottle Sodium Alginate Solution.
16 oz. bottle Calcium Chloride Solution.
Supplied sterilised, ready for use. Can be re-sterilised if desired by autoclaving.

*1948 *Lancet* I.893.

For full particulars and supplies of all Calgitex Alginate products please write to:—

ANAHÆMIN B.D.H.

The treatment of pernicious anæmia with Anahæmin B.D.H. is characterised by—

1 the small volume of effective doses
2 the infrequency of maintenance doses
3 comparative freedom from reactions

Each batch of Anahæmin B.D.H. is clinically tested before issue.

IZAL
GERMICIDE

For more than half a century Newton Chambers, the makers of Izal Products, have devoted their skill and research to the safeguarding of public health

Newton, Chambers & Co. Ltd., Thorncliffe, Sheffield

FOR THE BUSY PRACTITIONER

The convenience of tablet medication is undoubtedly of marked value in the treatment of many conditions presented daily to the physician.

This is particularly true of alkaline therapy, where 'Milk of Magnesia' Tablets are a frequent and everyday prescription. In the busy dispensary, or for providing immediate symptomatic relief while visiting the patient's home, they present advantages readily appreciated by the practitioner.

Quickly dispensed, accurate in dosage and convenient to take during working hours, 'Milk of Magnesia' Tablets offer a simple yet efficacious means of combating gastric upset due to hyperchlorhydria.

SPECIAL PROFESSIONAL PACKS

For personal, surgery or dispensing use, a professional pack of 'Milk of Magnesia' Tablets is available. This contains 500 Tablets and costs 10/- (including tax) post free. Orders should be sent direct.

'MILK OF MAGNESIA' TABLETS

THE CHAS. H. PHILLIPS CHEMICAL CO., LTD., 1, WARPLE WAY, LONDON, W.3

Section VI	Internal Medicine	*Section XIII*	Dermatology and Venereology
Section VII	Pediatrics	*Section XIV*	Radiology
		Section XV	Tuberculosis

The Lancet. '. . . The difficulties of collecting, every month, several thousands of abstracts, all needing careful editing, and many requiring translation into English, are not small, but the first two sections to issue their maiden numbers—*Dermatology and Venereology* and *Radiology*—show that a high standard has been set, and it seems likely that the *Excerpta Medica* will prove an important agent for disseminating knowledge of medicine.'

The British Journal of Radiology. '. . . The conception and execution of the scheme should command nothing but the highest admiration. . . . The serious student of both diagnostic and therapeutic radiology will find this publication essential for keeping abreast of the literature because, indeed, it is impossible to conceive of any other way of doing so.'

Write for a prospectus, or specimen copy of the section you require to

EXCERPTA MEDICA

FIFTEEN JOURNALS CONTAINING PERTINENT AND RELIABLE ABSTRACTS IN ENGLISH OF ALL ARTICLES IN THE FIELDS OF CLINICAL AND EXPERIMENTAL MEDICINE FROM EVERY AVAILABLE MEDICAL JOURNAL IN THE WORLD

Section I	Anatomy, Anthropology, Embryology and Histology	*Section VIII*	Neurology and Psychiatry
Section II	Physiology, Biochemistry and Pharmacology	*Section IX*	Surgery
Section III	Endocrinology	*Section X*	Obstetrics and Gynæcology
Section IV	Medical Microbiology and Hygiene	*Section XI*	Oto-, Rhino-, Laryngology
Section V	General Pathology and Pathological Anatomy	*Section XII*	Ophthalmology
Section VI	Internal Medicine	*Section XIII*	Dermatology and Venereology
Section VII	Pediatrics	*Section XIV*	Radiology
		Section XV	Tuberculosis

The Lancet. '. . . The difficulties of collecting, every month, several thousands of abstracts, all needing careful editing, and many requiring translation into English, are not small, but the first two sections to issue their maiden numbers—*Dermatology and Venereology* and *Radiology*—show that a high standard has been set, and it seems likely that the *Excerpta Medica* will prove an important agent for disseminating knowledge of medicine.'

The British Journal of Radiology. '. . . The conception and execution of the scheme should command nothing but the highest admiration. . . . The serious student of both diagnostic and therapeutic radiology will find this publication essential for keeping abreast of the literature because, indeed, it is impossible to conceive of any other way of doing so.'

Write for a prospectus, or specimen copy of the section you require to

Dietary Deficiencies

Although there seems to be no evidence of severe malnutrition in this country at the present time, there are, in individual cases, manifestations such as lack of concentration, lassitude, chronic fatigue and nervous disorders, which appear to be caused by inadequate diets. Some of these symptoms may be signs of a deficiency of the B vitamins.

Marmite is a yeast extract containing naturally-occurring riboflavin (1.5 mg. per oz.) and niacin (16.5 mg. per oz.) as well as other factors of the B$_2$ group derived from yeast; these include pyridoxin, pantothenic acid, choline, biotin and folic acid.

The dietetic value of Marmite has long been recognised; it is prescribed extensively as a prophylactic measure in combating malnutrition.

MARMITE

YEAST EXTRACT

Brand's Essence
(of Meat)

... has been recommended by doctors for over 100 years. It contains 10% of soluble meat protein, is free from fat and carbohydrate, and has a low salt content.

Because it is rapidly absorbed, owing to the perfect state of solution of the protein, it makes no demands on the digestive system and can be given in cases of acute digestive disorder. Brand's Essence is unrivalled as an aid to convalescence after serious illness. From chemists, 3/- a jar.

PROTECTING YOUNG TEETH

In recommending a dentifrice for children's use, three major factors will influence your selection.

(a) It is of obvious importance that the cleansing agents employed should be completely free of abrasive action.

(b) Powerful astringents are contra-indicated, as these may irritate and inflame the gum membrane.

(c) The essential oils incorporated must have a pleasant appeal to the young patient.

In all these respects, Phillips' Dental Magnesia presents a dentifrice which can, with confidence, be recommended to children of all ages. Completely free from harmful ingredients, it possesses a unique flavour which makes a very strong appeal to the young. Phillips' Dental Magnesia has, moreover, the outstanding property of inhibiting oral acidity by reason of the 'Milk of Magnesia'★ content, a very real advantage in protecting young teeth.

Phillips' Dental Magnesia (Regd.)

THE CHAS. H. PHILLIPS CHEMICAL CO., LTD. 1, WARPLE WAY, LONDON, W.3.

★ *'Milk of Magnesia' is the trade mark of Phillips' preparation of magnesia.*

ANAHÆMIN B.D.H.

The treatment of pernicious anæmia with Anahæmin B.D.H. is characterised by—

1 the small volume of effective doses
2 the infrequency of maintenance doses
3 comparative freedom from reactions

Each batch of Anahæmin B.D.H. is clinically tested before issue.

ALLEN & UNWIN

Books by CHARLES BERG

Clinical Psychology

This brilliant and detailed review of the whole subject of clinical psychology concludes with a critical analysis of past treatment and revolutionary suggestions for the future. It is a case book of the neuroses and their treatment and cites examples from the simplest worries and anxieties, through increasing severity of stresses, to incipient major disorders. Straightforward, realistic and fascinating, the reader will hardly realise how much information he is assimilating. It is a book that every doctor can read and enjoy.

500 *pages.* 25s. net

Deep Analysis

The complete analysis of an individual case which throws considerable light upon the working of the human mind.

"There is no article or book we know of which puts on record quite so clearly how psychoanalytic interviews are conducted, and it can be warmly commended."—*The Practitioner.*

EXCERPTA MEDICA

FIFTEEN JOURNALS CONTAINING PERTINENT AND RELIABLE ABSTRACTS IN ENGLISH OF ALL ARTICLES IN THE FIELDS OF CLINICAL AND EXPERIMENTAL MEDICINE FROM EVERY AVAILABLE MEDICAL JOURNAL IN THE WORLD

Section I	Anatomy, Anthropology, Embryology and Histology	*Section VIII*	Neurology and Psychiatry
Section II	Physiology, Biochemistry and Pharmacology	*Section IX*	Surgery
Section III	Endocrinology	*Section X*	Obstetrics and Gynæcology
Section IV	Medical Microbiology and Hygiene	*Section XI*	Oto-, Rhino-, Laryngology
Section V	General Pathology and Pathological Anatomy	*Section XII*	Ophthalmology
Section VI	Internal Medicine	*Section XIII*	Dermatology and Venereology
Section VII	Pediatrics	*Section XIV*	Radiology
		Section XV	Tuberculosis

The Lancet. '. . . The difficulties of collecting, every month, several thousands of abstracts, all needing careful editing, and many requiring translation into English, are not small, but the first two sections to issue their maiden numbers—*Dermatology and Venereology* and *Radiology*—show that a high standard has been set, and it seems likely that the *Excerpta Medica* will prove an important agent for disseminating knowledge of medicine.'

The British Journal of Radiology. '. . . The conception and execution of the scheme should command nothing but the highest admiration. . . . The serious student of both diagnostic and therapeutic radiology will find this publication essential for keeping abreast of the literature because, indeed, it is impossible to conceive of any other way of doing so.'

Write for a prospectus, or specimen copy of the section you require to

Sole distributors for Great Britain and the British Dominions

DIETARY DEFICIENCIES

Although there seems to be no evidence of severe malnutrition in this country at the present time there are, in individual cases, manifestations such as lack of concentration, lassitude, chronic fatigue and nervous disorders, which appear to be caused by inadequate diets. Some of these symptoms may be signs of a deficiency of the B vitamins.

Marmite is a yeast extract containing naturally-occurring riboflavin (1.5 mg. per oz.) and niacin (16.5 mg. per oz.) as well as other factors of the B_2 group derived from yeast; these include pyridoxin, pantothenic acid, choline, biotin and folic acid.

The dietetic value of Marmite has long been recognised; it is prescribed extensively as a prophylactic measure in combating malnutrition.

MARMITE

yeast extract

Jars: 1-oz. 8d., 2-oz. 1/1, 4-oz. 2/-, 8-oz. 3/3, 16-oz. 5/9. Obtainable from Chemists and Grocers
Special terms for packs for hospitals, welfare centres and schools

Improved Nutrition

It is now widely recognised that a good diet is of paramount importance for the maintenance of health. But, while it is well known that proteins, fats, carbohydrates, vitamins and mineral salts are essential nutrients, it seems desirable that more information should be made available concerning the composition of the different foods, in order to encourage an intelligent planning of the diet and thus improve the general standard of nutrition.

Marmite is a yeast extract containing naturally-occurring riboflavin (1·5 mg. per oz.) and niacin (16·5 mg. per oz.) as well as other factors of the B_2 complex derived from yeast; these include pyridoxin, pantothenic acid, choline, biotin and folic acid.

MARMITE

yeast extract

London Medical Exhibition
November 15th—19th

Improved Nutrition

It is now widely recognised that a good diet is of paramount importance for the maintenance of health. But, while it is well known that proteins, fats, carbohydrates, vitamins and mineral salts are essential nutrients, it seems desirable that more information should be made available concerning the composition of the different foods, in order to encourage an intelligent planning of the diet and thus improve the general standard of nutrition.

Marmite is a yeast extract containing naturally-occurring riboflavin (1·5 mg. per oz.) and niacin (16·5 mg. per oz.) as well as other factors of the B_2 complex derived from yeast; these include pyridoxin, pantothenic acid, choline, biotin and folic acid.

MARMITE

yeast extract

Obtainable from Chemists and Grocers
Jars: 1-oz. 8d., 2-oz. 1/1, 4-oz. 2/-, 8-oz. 3/3, 16-oz. 5/9
Special terms for packs for hospitals, welfare centres and schools

Literature on application

489/b THE MARMITE FOOD EXTRACT CO. LTD., 35, Seething Lane, LONDON, E.C.3

RHEUMATISM

and allied disorders

Where salicylate therapy is indicated, toxic symptoms, such as hæmorrhage, urticaria, and capillary permeability, may be avoided by the simultaneous administration of menaphthone and ascorbic acid.

"EKAMMON"

is the product of choice

because it provides, in tablet form, an easily administered and scientifically balanced combination of acetylsalicylic acid (0·33 gm.), ascorbic acid (20 mgm.) and menaphthone (0·33 mgm.).

Full details concerning "EKAMMON" in the treatment of acute and chronic rheumatism, with extensive bibliography, available on request.

A SURGEON'S LIFE *

Sir Heneage Ogilvie

K.B.E., D.M. Oxfd, F.R.C.S., F.A.C.S., F.R.C.S.C. F.R.A.C.S.

SURGEON TO GUY'S HOSPITAL

What is the life of a surgeon ? How does it differ from that of a physician ? What characters distinguish the two great branches of medicine, and what circumstances prompt an individual to select one or the other ? Where does the watershed lie that divides the diseases which are the province of the physician from those which are cared for by the surgeon ?

Surgery has been defined as the art of treating injuries and diseases by manual operations. These operations are local manœuvres applied to part of the body only, and they deal almost necessarily with localised trauma or with disease that is local or, if general, demands treatment because of some local manifestation. The main problems presented to the surgeon are the repair of injuries, the setting of fractures, the arrest of hæmorrhage, the closure of wounds ; the treatment of local sepsis by drainage ; the removal of stones, areas of diseased tissues, innocent tumours, or malignant tumours while they are still confined to one part of the body ; the overcoming of obstruction in a natural passage by excision or drainage ; the correction of malformations and deformities ; the redress of overaction in the endocrine or autonomic systems ; the combating of local circulatory failure ; the replacement of defects by grafting ; and the relief of pain by the division of nerves or by the anatomical or functional elimination of its source. Thus surgery offers a considerable variety of tasks, but in this catalogue two common factors can be [illegible]. First, the ailments enumerated are localised not merely in space but in time ; they involve part of a body the rest of which is healthy, and they come as temporary clouds in the sky of a life that has been clear and will be clear again. Secondly, the cure or relief depends largely or entirely on the action of the surgeon himself.

In contrast, the diseases which the physician treats usually affect the whole patient, either directly or indirectly, by the effect of the local lesion on his health, and they affect him not transitorily but for long periods, often for the rest of a life that they are destined to terminate prematurely. In the medical wards we find generalised infections by virus, bacteria, or parasites ; chronic and progressive failure of the digestive, absorptive, excretory, respiratory, or circulatory systems ; widespread damage due to the action of exogenous or endogenous toxins ; congenital and often hereditary maldevelopments of organs, systems, or tissues ; endocrine imbalance ; deficiency diseases ; and degenerative processes. There is little active that the physician can do towards the cure of these sufferers, though the advances in specific chemotherapy have given him a measure of control over some of the acute infections. He can by the prescription of rest and diet help the natural tendency of healthy tissues to fight their own battles, but too often his task is limited to that of the investigator and pinner of labels, the spectator of a losing battle in which he cannot help, the dispenser of encouragement that can cheer but cannot cure.

The medical ward is as cheerful as planned surroundings and the efforts of the nurses can make it, but the prevailing note is one of sympathy rather than optimism. In contrast the surgical ward is a cheerful and even a boisterous place. The patients look forward to an early return to their homes in better condition than when they arrived, and meanwhile do what they can to show their gratitude by helping in the ward and cheering up the lonely or apprehensive newcomer.

Surgery thus attracts the man whose interest in medicine is humanitarian rather than scientific, who loves his fellow men, who wishes to help them and to see that his help is effective. It appeals to the craftsman who enjoys the use of his hands, to the artist whose mind works on visual images, to the romantic who enjoys the drama of life, particularly when it affords him the opportunity to play a decisive rôle, to the extrovert. The president of the residents, the footballer, the mountaineer, the yachtsman, are drawn instinctively towards the surgical side of practice. The prizewinner, the editor of the hospital journal, the debater, the naturalist, tend to find their vocation in medicine.

PERSONAL RESPONSIBILITY

Entered on his chosen work, the surgeon finds those qualities that brought him into surgery further developed by its exercise. Because his patients, for the most part, suffer from local lesions of recent development that have not affected their general health or been accepted by them as part of their environment, he is consulted more urgently, more personally, than the physician. His help is needed as a friend and his advice as a counsellor, almost as much as his opinion is sought as an expert.

The guiding circumstance of a surgeon's life is personal responsibility. He is in charge, he must make decisions and initiate or carry out the line of action those decisions imply, and on the correctness of his decisions and the skill and determination with which the action is carried out depends the welfare and possibly the life of his patient. All the material for a correct diagnosis may not be available, at any rate at a particular time, but there must always be a decision : even though it may not be the right one it is the best that can be made at the time and the one on which action must be based if action is needed.

A surgeon conducting a difficult case is like the skipper of an ocean-going racing yacht. He knows the port he must make, but he cannot foresee the course of the journey. He must be guided as he goes by changes of wind and weather, he must constantly seek help from the barometer, the lead, the look of the sky, the B.B.C. weather forecast, and he must plan his course not so much to give the most direct journey as at all stages to avoid possible dangers. At every point he must know how far he has travelled, where he is, and the limits of error within which his projected position may lie ; what dangers and difficulties lie immediately ahead ; and how soon he may expect to make port. At every stage he must have a plan, based on a working knowledge of his present position, that will allow him to make for the best of several available harbours should things go wrong, or if none is suitable he must know where to find temporary refuge under the lee of the land till he can resume his journey.

The physician's task is more comparable to that of the golfer. He may know the course and the hole he is playing from long familiarity, or he may for the first time be playing a difficult dog-leg hole on a strange course. If he judges the direction and the wind right, estimates each lie correctly, finds the right club for each shot and uses it skilfully, he will get a bogie or a birdie. If he makes a mistake he will make a poor score, but will get there in the end. The ground will not split beneath his feet, the game will not change suddenly from golf to bull-fighting. The ball may be lost, but that is a way balls have on rough courses.

In urgent surgery, particularly that of abdominal emergencies, the surgeon is constantly being called on for decisions based on his estimate of the probable course of events rather than on demonstrable facts and an unequivocal diagnosis. He must often ask himself which

Why 'Ribena' in Gum Infections?

Because the satisfactory results from clinical tests with Ribena have confirmed the belief that hypovitaminosis C predisposes to defective dentition and gum infections. Because, moreover, *natural* vitamin C, in the form of blackcurrant syrup, has been shown by practical experience to be a most valuable adjunct to local therapy in ulcerative stomatitis. Further, more specific, information will be gladly supplied to members of the medical profession.

Ribena is the pure undiluted juice of fresh ripe blackcurrants with sugar, in the form of a delicious syrup. Being freed from all cellular structure of the fruit, it cannot upset the most delicate stomach. It is particularly rich in natural vitamin C (not less than 20 mgm. per fluid ounce) and associated factors.

Ribena BLACKCURRANT SYRUP

INCREASED PREVALENCE OF HYPERACIDITY

One legacy of war-time strain persists. It is evidenced by the number of patients exhibiting symptoms of gastro-intestinal disorder.

The same stress factors of overwork, hurried, irregular meals and the inability to relax completely still prevail.

In such instances, 'Milk of Magnesia' is invaluable in securing rapid control of discomfort. A colloidal suspension of magnesium hydroxide, it soothes the inflamed mucosa, and neutralizes the excess acid, without liberation of gas. Furthermore, its mild laxative action ensures removal of toxic waste products.

'Milk of Magnesia' may be prescribed with confidence equally in the mild case of dyspepsia or the acute ulcer stage where sustained alkaline treatment is essential.

SURGEON TO GUY'S HOSPITAL

What is the life of a surgeon? How does it differ from that of a physician? What characters distinguish the two great branches of medicine, and what circumstances prompt an individual to select one or the other? Where does the watershed lie that divides the diseases which are the province of the physician from those which are cared for by the surgeon?

Surgery has been defined as the art of treating injuries and diseases by manual operations. These operations are ocal manœuvres applied to part of the body only, and hey deal almost necessarily with localised trauma or with disease that is local or, if general, demands treatment because of some local manifestation. The main problems presented to the surgeon are the repair of njuries, the setting of fractures, the arrest of hæmorrhage, he closure of wounds; the treatment of local sepsis by drainage: the removal of stones, areas of diseased issues, innocent tumours, or malignant tumours while hey are still confined to one part of the body: the overcoming of obstruction in a natural passage by excision or drainage; the correction of malformations and deformities; the redress of overaction in the endocrine or autonomic systems: the combating of ocal circulatory failure: the replacement of defects by grafting; and the relief of pain by the division of nerves or by the anatomical or functional elimination of its source. Thus surgery offers a considerable variety of tasks, but in this catalogue two common factors can be d. First, the ailments enumerated are localised not merely in space but in time; they involve part of a body the rest of which is healthy, and they come as temporary louds in the sky of a life that has been clear and will be clear again. Secondly, the cure or relief depends largely or entirely on the action of the surgeon himself.

In contrast, the diseases which the physician treats usually affect the whole patient, either directly or indirectly, by the effect of the local lesion on his health, and they affect him not transitorily but for long periods, often for the rest of a life that they are destined to terminate prematurely. In the medical wards we find generalised infections by virus, bacteria, or parasites; chronic and progressive failure of the digestive, absorptive, excretory, respiratory, or circulatory systems; widespread damage due to the action of exogenous or endogenous toxins; congenital and often hereditary maldevelopments of organs, systems, or tissues; endocrine imbalance; deficiency diseases; and degenerative processes. There is little active that the physician can do towards the cure of these sufferers, though the advances n specific chemotherapy have given him a measure of control over some of the acute infections. He can by the prescription of rest and diet help the natural tendency of healthy tissues to fight their own battles, but too often his task is limited to that of the investigator and pinner of labels, the spectator of a losing battle in which he cannot help, the dispenser of encouragement that can heer but cannot cure.

The medical ward is as cheerful as planned surroundngs and the efforts of the nurses can make it, but the prevailing note is one of sympathy rather than optimism. n contrast the surgical ward is a cheerful and even a boisterous place. The patients look forward to an early eturn to their homes in better condition than when hey arrived, and meanwhile do what they can to show their gratitude by helping in the ward and cheering up the lonely or apprehensive newcomer.

Surgery thus attracts the man whose interest in medicine is humanitarian rather than scientific, who loves his fellow men, who wishes to help them and to see that his help is effective. It appeals to the craftsman who enjoys the use of his hands, to the artist whose mind works on visual images, to the romantic who enjoys the drama of life, particularly when it affords him the opportunity to play a decisive rôle, to the extrovert. The president of the residents, the footballer, the mountaineer, the yachtsman, are drawn instinctively towards the surgical side of practice. The prizewinner, the editor of the hospital journal, the debater, the naturalist, tend to find their vocation in medicine.

PERSONAL RESPONSIBILITY

Entered on his chosen work, the surgeon finds those qualities that brought him into surgery further developed by its exercise. Because his patients, for the most part, suffer from local lesions of recent development that have not affected their general health or been accepted by them as part of their environment, he is consulted more urgently, more personally, than the physician. His help is needed as a friend and his advice as a counsellor, almost as much as his opinion is sought as an expert.

The guiding circumstance of a surgeon's life is personal responsibility. He is in charge, he must make decisions and initiate or carry out the line of action those decisions imply, and on the correctness of his decisions and the skill and determination with which the action is carried out depends the welfare and possibly the life of his patient. All the material for a correct diagnosis may not be available, at any rate at a particular time, but there must always be a decision: even though it may not be the right one it is the best that can be made at the time and the one on which action must be based if action is needed.

A surgeon conducting a difficult case is like the skipper of an ocean-going racing yacht. He knows the port he must make, but he cannot foresee the course of the journey. He must be guided as he goes by changes of wind and weather, he must constantly seek help from the barometer, the lead, the look of the sky, the B.B.C. weather forecast, and he must plan his course not so much to give the most direct journey as at all stages to avoid possible dangers. At every point he must know how far he has travelled, where he is, and the limits of error within which his projected position may lie: what dangers and difficulties lie immediately ahead; and how soon he may expect to make port. SURGEON TO GUY'S HOSPITAL

WHAT is the life of a surgeon ? How does it differ rom that of a physician ? What characters distinguish he two great branches of medicine, and what circumstances prompt an individual to select one or the other ? Where does the watershed lie that divides the diseases which are the province of the physician from those which are cared for by the surgeon ?

Surgery has been defined as the art of treating injuries and diseases by manual operations. These operations are local manœuvres applied to part of the body only, and they deal almost necessarily with localised trauma or with disease that is local or, if general, demands treatment because of some local manifestation. The main problems presented to the surgeon are the repair of injuries, the setting of fractures, the arrest of hæmorrhage, the closure of wounds ; the treatment of local sepsis by drainage ; the removal of stones, areas of diseased tissues, innocent tumours, or malignant tumours while they are still confined to one part of the body ; the overcoming of obstruction in a natural passage by excision or drainage ; the correction of malformations and deformities ; the redress of overaction in the endocrine or autonomic systems ; the combating of local circulatory failure ; the replacement of defects by grafting ; and the relief of pain by the division of nerves or by the anatomical or functional elimination of its source. Thus surgery offers a considerable variety of tasks, but in this catalogue two common factors can be traced. First, the ailments enumerated are localised not merely in space but in time ; they involve part of a body the rest of which is healthy, and they come as temporary clouds in the sky of a life that has been clear and will be clear again. Secondly, the cure or relief depends largely or entirely on the action of the surgeon himself.

In contrast, the diseases which the physician treats usually affect the whole patient, either directly or indirectly, by the effect of the local lesion on his health, and they affect him not transitorily but for long periods, often for the rest of a life that they are destined to terminate prematurely. In the medical wards we find generalised infections by virus, bacteria, or parasites ; chronic and progressive failure of the digestive, absorptive, excretory, respiratory, or circulatory systems ; widespread damage due to the action of exogenous or endogenous toxins ; congenital and often hereditary maldevelopments of organs, systems, or tissues ; endocrine imbalance ; deficiency diseases ; and degenerative processes. There is little active that the physician can do towards the cure of these sufferers, though the advances in specific chemotherapy have given him a measure of control over some of the acute infections. He can by the prescription of rest and diet help the natural tendency of healthy tissues to fight their own battles, but too often his task is limited to that of the investigator and pinner of labels, the spectator of a losing battle in which he cannot help, the dispenser of encouragement that can cheer but cannot cure.

The medical ward is as cheerful as planned surroundings and the efforts of the nurses can make it, but the prevailing note is one of sympathy rather than optimism. In contrast the surgical ward is a cheerful and even a boisterous place. The patients look forward to an early return to their homes in better condition than when they arrived, and meanwhile do what they can to show their gratitude by helping in the ward and cheering up the lonely or apprehensive newcomer.

Surgery thus attracts the man whose interest in medicine is humanitarian rather than scientific, who loves his fellow men, who wishes to help them and to see that his help is effective. It appeals to the craftsman who enjoys the use of his hands, to the artist whose mind works on visual images, to the romantic who enjoys the drama of life, particularly when it affords him the opportunity to play a decisive rôle, to the extrovert. The president of the residents, the footballer, the mountaineer, the yachtsman, are drawn instinctively towards the surgical side of practice. The prizewinner, the editor of the hospital journal, the debater, the naturalist, tend to find their vocation in medicine.

PERSONAL RESPONSIBILITY

Entered on his chosen work, the surgeon finds those qualities that brought him into surgery further developed by its exercise. Because his patients, for the most part, suffer from local lesions of recent development that have not affected their general health or been accepted by them as part of their environment, he is consulted more urgently, more personally, than the physician. His help is needed as a friend and his advice as a counsellor, almost as much as his opinion is sought as an expert.

The guiding circumstance of a surgeon's life is personal responsibility. He is in charge, he must make decisions and initiate or carry out the line of action those decisions imply, and on the correctness of his decisions and the skill and determination with which the action is carried out depends the welfare and possibly the life of his patient. All the material for a correct diagnosis may not be available, at any rate at a particular time, but there must always be a decision ; even though it may not be the right one it is the best that can be made at the time and the one on which action must be based if action is needed.

A surgeon conducting a difficult case is like the skipper of an ocean-going racing yacht. He knows the port he must make, but he cannot foresee the course of the journey. He must be guided as he goes by changes of wind and weather, he must constantly seek help from the barometer, the lead, the look of the sky, the B.B.C. weather forecast, and he must plan his course not so much to give the most direct journey as at all stages to avoid possible dangers. At every point he must know how far he has travelled, where he is, and the limits of error within which his projected position may lie ; what dangers and difficulties lie immediately ahead ; and how soon he may expect to make port. At every stage he must have a plan, based on a working knowledge of his present position, that will allow him to make for the best of several available harbours should things go wrong, or if none is suitable he must know where to find temporary refuge under the lee of the land till he can resume his journey.

The physician's task is more comparable to that of the golfer. He may know the course and the hole he is playing from long familiarity, or he may for the first time be playing a difficult dog-leg hole on a strange course. If he judges the direction and the wind right, estimates each lie correctly, finds the right club for each shot and uses it skilfully, he will get a bogie or a birdie. If he makes a mistake he will make a poor score, but will get there in the end. The ground will not split beneath his feet, the game will not change suddenly from golf to bull-fighting. The ball may be lost, but that is a way balls have on rough courses.

In urgent surgery, particularly that of abdominal emergencies, the surgeon is constantly being called on for decisions based on his estimate of the probable course of events rather than on demonstrable facts and an unequivocal diagnosis. He must often ask himself which

Why 'Ribena' in Gum Infections?

Because the satisfactory results from clinical tests with Ribena have confirmed the belief that hypovitaminosis C predisposes to defective dentition and gum infections. Because, moreover, *natural* vitamin C, in the form of blackcurrant syrup, has been shown by practical experience to be a most valuable adjunct to local therapy in ulcerative stomatitis. Further, more specific, information will be gladly supplied to members of the medical profession.

Ribena is the pure undiluted juice of fresh ripe blackcurrants with sugar, in the form of a delicious syrup. Being freed from all cellular structure of the fruit, it cannot upset the most delicate stomach. It is particularly rich in natural vitamin C (not less than 20 mgm. per fluid ounce) and associated factors.

REVISED EDITIONS FROM CASSELL

DISEASES OF THE EYE

by EUGENE WOLFF
M.B., B.Sc. Lond., F.R.C.S. Eng.

New Third revised edition, Crown Quarto, 5 colour plates, 133 text illustrations. 21*s. net*

"For the student or general practitioner wanting a general survey of ophthalmology the book is unequalled at present."
—*Lancet.* (On the 2nd Edition)

DISEASES OF THE NOSE AND THROAT

by SIR ST. CLAIR THOMSON
M.D., F.R.C.P. Lond., F.R.C.S.
and V. E. NEGUS
M.S. Lond., F.R.C.S. Eng.

New Fifth revised edition, Royal 8vo, 1024 *pp.,* 44 *plates,* 13 *in colour,* 369 *text illustrations.* 70*s. net*

THOMSON-WALKER'S

GENITO-URINARY SURGERY

Revised by KENNETH WALKER
O.B.E., F.R.C.S. Eng.

New Third revised edition, Royal 8vo. 974 *pp.,* 58 *plates,* 25 *in colour,* 280 *text illustrations.* 60*s. net*

INCREASED PREVALENCE OF HYPERACIDITY

One legacy of war-time strain persists. It is evidenced by the number of patients exhibiting symptoms of gastro-intestinal disorder.

The same stress factors of overwork, hurried, irregular meals and the inability to relax completely still prevail.

In such instances, 'Milk of Magnesia' is invaluable in securing rapid control of discomfort. A colloidal suspension of magnesium hydroxide, it soothes the inflamed mucosa, and neutralizes the excess acid, without liberation of gas. Furthermore, its mild laxative action ensures removal of toxic waste products.

'Milk of Magnesia' may be prescribed with confidence equally in the mild case of dyspepsia or the acute ulcer stage where sustained alkaline treatment is essential.

'MILK OF MAGNESIA'

enterprise of one man or a group of men, but it tends to be perpetuated by men of a different type. It is against the closed shop, designed to keep the privileges and emoluments of practice to those within the fold, removing its recruits at an early age from the competitive struggle of general medicine and surgery, and tending therefore to attract men in search of safety and an assured income rather than of adventure and discovery, that criticism must be levelled.

But specialisms are not all subdivisions either of medicine or of surgery. There are branches of practice, of which gynæcology, ophthalmology, and otolaryngology are the best examples, in which medicine and surgery are equally blended, and in which physiology becomes more important than anatomy. In surgery one-system specialisms are developing apace. The neurosurgeon is now a neurologist; the thoracic surgeon is an expert at physical signs and the interpretation of radiograms, a student of the physiology of the circulatory and respiratory systems, and a physician skilled at their disorders. The gastric and the proctological surgeons are tending more and more to be their own physicians. They are in one sense becoming more specialised, in another more general. Which way does advance lie?

Medicine as a whole is too vast for the grasp of any one individual. Specialism is inevitable, and having accepted it we must examine its limitations. The essential and inescapable one is that a specialist is expert for one purpose only. A specialist alone can be supremely efficient, and the earlier he devotes himself to a particular branch of study, the smaller that branch, and the more single-minded the devotion with which he studies it, the more efficient will he be in that branch and that alone. But disease is no specialist. Patients do not consult us because certain organs are affected, but because they feel ill. They come with symptoms, and the earlier and therefore the more curable their malady is, the more vague will those symptoms be, the more difficult the elucidation of their cause, the greater the need, in the first place, of a general investigation by one whose daily practice covers the whole of disease.

Even in the study of one disease it is doubtful if specialism necessarily leads to surgical skill of the highest order. We hear today of thyroid specialists. What is a thyroid specialist? Is he necessarily better than the non-specialist thyroidectomist? Indeed is he often as good? Will not the surgeon accustomed to operate in all parts of the body, if he specialises in good technique, if he performs the operation for the first few times under apprenticeship and afterwards undertakes it often enough not to forget what he has learnt, do it better than the man who pursues it day after day with single-minded attention? The latter is only too likely to degenerate into that dangerous Pooh-bah the thyroid expert—surgeon, physician, gynæcologist, psychologist, endocrinologist, physiologist, and hæmatologist in one.

The surgeon who is his own physician, though he often has a fool for a colleague, has the happiness of working in an atmosphere of mutual confidence and admiration. He is, however, apt to go astray in departments of surgery, such as those dealing with the treatment of thyroid diseases and of hypertension, in which the decision to operate involves a general assessment on the widest grounds, and in which the operation demands careful workmanship and close attention to detail. In these the surgeon's chief duty is to be an expert craftsman. He should know enough to understand what his medical colleague is talking about, enough to argue with him intelligently, enough even on rare occasions to disagree flatly with his conclusions; but, the decision having been reached, his rôle should be that of the technician, seeking to attain the objects which the physician has found to be most desirable by the means he knows to be most certain and most safe.

THE MEASURE OF GREATNESS

Such are the men who enter surgery, and such are the paths open to them when they have made their choice. What of the journey—their life? Some plod wearily along it and some fall out: most march on gladly and hopefully: a few travel triumphantly ahead, smoothing the path as they go and giving fresh heart to those who follow them.

> "Lives of great men all remind us
> We can make our lives sublime,
> And, departing, leave behind us
> Footprints on the sands of time."

Who have been the great men of surgery? As we look into the past, great names crowd upon us, and we can speak only of a few of them. There are those whose lives are now matters of history—Thomas Vicary and Ambroise Paré, Hunter and Astley Cooper, Syme, Ferguson and Liston, Benjamin Brodie, Pott and Paget, Lister, Spencer Wells, Lawson Tait, Jonathan Hutchison, Hugh Owen Thomas, Von Mikulicz, Billroth, Trendelenburg, Dupuytren. There are others whose names are more recent in our memory, who have been seen and heard by many of us—Macewen, Rutherford Morison, Trotter, Lane, the Mayos, Cushing, Halsted, Murphy, Kocher, von Eiselsberg, and Kirschner. And there are those still with us—Matas, Gallie, Evarts Graham, Frank Lahey, Danis, Gordon Taylor, Sampson Handley, Grey Turner, Henry Wade, Gillies, Jefferson, Zachary Cope, John Morley, and Harry Platt—all secure of their niche in Valhalla, and others, our contemporaries and juniors, whose names are now pinned on the notice-board for consideration. What have these men in common?

In judging a surgeon we must consider qualities of the head, the heart, and the hand. We must consider his knowledge of the basic sciences on which surgery is founded, of the history of surgery, of contemporary literature on his own and related subjects, knowledge based not on reading alone but also on travel and on constant intercourse with his fellows. We must consider his wisdom—that is, his capacity to blend the knowledge gained from reading and from his own experience into a clinical common sense which he is able to apply to his daily problems as they arise, his readiness to look on surgery as a whole, and to see it in relation to the great body of science. We must consider his originality, his power to see a common factor linking scattered observations and to follow the path those observations blaze to fresh knowledge, to see the fallacies in old methods and to plan new ones; his ability to avoid complacency and to preserve throughout life an attitude of alert and adventurous expectancy. We must include in qualities of the mind his power to instruct by word of mouth or pen, to see through the trappings of a matter its essential core, to write clearly and speak convincingly.

Of qualities of the heart that a surgeon must possess the first is humility. The great surgeon is humble by nature, because the things he has done count for him as very little in comparison with the great mass of the things that yet remain to be done. He is slow to criticise others, yet tolerant of those who criticise him. He has an instinctive love of his fellowmen, a sympathy that considers each case as a human problem requiring individual treatment, a human understanding that can interpret the patient's halting story in terms of the sorrow, hopes, and fears that the words conceal. Because of his humility and human kindness he is approachable to his juniors. He must have courage to undertake the desperate risk and, having failed, to study why he failed and undertake it again. He must be prepared to face unpopularity and even failure in the pursuit of what he believes to be right, to meet censure and ignore it if he knows it to be unfounded.

Lastly we must consider his manual skill, for in the use of his hands his other qualities find their final expression, of several possible courses is the most dangerous if not the most likely, and therefore the one which must guide his actions. Before he decides to await fresh evidence he must consider whether the patient's state is likely to improve or to get worse in the interval. To the relations he must often say: "I do not yet know what is wrong, but it is something serious, and it is getting worse. Even in this uncertainty I advise an operation, because I believe its risks to be less than those of continued waiting, and because I know it will tell us what is the matter and probably allow us to put it right."

Even in matters of no urgency, where life and death are not at stake, a decision based on half-knowledge and intuition is often needed. A lump of doubtful nature, but clearly innocent, may be found in a young woman's breast. Should it be watched, or should it be removed? The answer is more in the realm of human relations than of pathology or diagnosis. Will she accept reassurance and forget her lump till the next visit, or will she be haunted by the fear of cancer night and day?

A girl may complain of slight digestive disturbances, and on several occasions may be found to be tender over an area the size of a two-shilling piece at McBurney's point and nowhere else. Observation of the temperature, blood-count, sedimentation-rate, and barium meal show no abnormality. Should the appendix be removed? Tell it not in the medical schools, but there is such a thing as chronic appendicitis. Tests will not show it, and the only proof is that at operation the appendix is found to be abnormal, and after it the patient is found to be well. The abnormality is not gross, but pathology differs from law in that it takes particular notice of small things. The chronically inflamed appendix when removed looks more opaque than the normal one, a dull white instead of a translucent pink; it is a little more rigid, and it can be bent but not tied in a half-hitch; it is more vascular, and the vessels are not limited to its attached margin but form a continuous crest along its *antimesenteric border*. The patient after its removal undergoes no dramatic change but merely says: "Now at last I am really well." These "chronic appendices," as distinct from the relapsing ones, have never been acute. They harbour a resident pathogenic organism, often a *streptococcus*. Though they usually give rise to no more than vague ill health they may be responsible for the most dramatic train of symptoms.

The removal of a chronic appendix can do nothing but good, and the removal of a normal appendix in all honesty can do no harm. On the other hand, there is no operation more disastrous than facile appendicectomy where the disease is in the patient's mind or the surgeon's morals. Here again the choice is philosophic rather than scientific, a decision rather than a diagnosis.

The surgeon, then, has been drawn to his life's work because of certain qualities born in him or developed by his upbringing. Because he is a doer rather than a thinker, because he seeks practical tools and hopeful tasks, because he enjoys helping and being helped by his fellowmen, he finds satisfaction and happiness in the corporate loyalty of a surgical team and the cheerful banter of a surgical ward. As the years go by he becomes fixed in the same mould. He seeks sports such as sailing, hunting, and mountaineering, in which companionship, manual skill, hard work, and a spice of danger are combined. He is seldom a profound reader, a good speaker, or a writer of distinction. The physician on the other hand tends to the solitary and sedentary pursuits, such as fishing and golf, to become a collector and a patron of the arts. I may perhaps be allowed to contrast the research laboratories, the extensive educational programme, the museum and library, the daily meals, evening refreshments, and students' hostels of Lincoln's Inn Fields with the formal eponymous lectures, traditional ceremony, and old-world dignity of Trafalgar Square.

SPECIALISATION

Life, however, is not quite so simple as it was described by the sentry in *Iolanthe*. Every boy and every gal that's born into this world alive is not necessarily a little liberal or else a little conservative; there are left-wing conservatives and Tory democrats, and between them the decisive mass of the *untied* electorate. The student is undoubtedly inclined by his natural qualities or early upbringing towards medicine or surgery, but his course thereafter is not immutably fixed like that of a drop of rain falling in the Black Forest, which may find its way down the Rhine to Rotterdam, or, if it falls a few yards to the north, will pass down the Danube and through the Black Sea and the Sea of Marmora to the Mediterranean. He will find at all stages of his career avenues leading from the main track, some taking him back to a highway which he had already rejected, others wandering through solitary and even unexplored country.

Specialisation is a word that has almost lost its meaning. Today all God's children are specialists—the man who cuts our hair, the man who mends our wireless, the man who cleans our chimneys. The term is used everywhere as a synonym for expert; but are specialisation and ability really synonymous? Is a specialist in one branch of an art, trade, or profession necessarily superior to the man who practises the whole of it? If so, is he at the same time inferior to one who practises a subdivision of that branch, and he in turn to one who confines his labours to one small aspect of *that* subdivision?

Specialisation arises in several ways. It may be called into being by the demands of the public, by the needs of the work, or by personal inclination. The public is always seeking what it believes to be the best, and having no standards of its own it will be guided by a label. Knowing nothing of degrees, appointments, published work, or established reputation, it flocks to the "Harley Street specialist," not realising that a brass plate sometimes represents nothing but brass, and that the Harley Street district, besides being the home of the elect, harbours many rogues. Having diagnosed its own disease, it seeks the "specialist" in that particular disease without being able to distinguish between the man who has made his own contribution to knowledge and the one who has set up his barrow where he suspects a good market. Public demand thus provides a reason but hardly a justification for specialism.

Specialism arises as an outcome of the needs of practice whenever new problems appear in medicine or surgery, or when old ones require further study because some fresh discovery has shed new light on them or initiated a new line of treatment. It is necessary in the case of diseases, methods of investigation, or operations so rare that only by segregation is it possible for them to be studied in series or viewed as a whole. It arises where investigation or treatment involves the use of instruments or methods alien to those of general medicine or surgery, whose use requires special skill or long apprenticeship. It arises too for convenience in segregating patients of one sex, or one age-group, in the practice of a hospital.

Most surgeons, in however general a way they have started and however "general" they may wish to remain, become to some extent specialists as they grow older, because they are attracted more and more to work of a special kind, because chance association or some feature of the district in which they work brings them many cases of a particular nature, or because they are recognised by their fellows as being unusually skilled in some form of treatment, and are asked to undertake it to an extent that practically excludes other work.

Such specialisation, which is the natural outcome of a man's inclinations and ability, is inevitable, indeed highly desirable. All specialism, whether medical or surgical, has originated thus in the vision, energy, and open to the password of ability of any kind. A first class in any honours school; a contribution to music, painting, sculpture, or literature considered meritorious by experts in that art; original work in history, biology, chemistry, or mechanics—all these should be accepted not as substitutes for the examination but as justifying a more lenient standard in the other part of it.

A qualifying examination is necessary, for it is essential that the recruit in any art or science shall, at the outset of his career, be familiar with the whole body of orthodox knowledge which has been built up by those before him and must form the platform from which he will start on his own career. He may in future diverge in any way he likes, but he should not, through ignorance, make mistakes that have already been made and corrected, or strive laboriously towards knowledge which is already available for the asking.

The final examination must be searching but it must be kind. It should seek to find out not what the candidate has been taught but what he has learnt for himself, not what he thinks but how he thinks. It should be kindly enough to put him at ease, and leisurely enough to allow the examiner to get past his nervousness and see through his bluff. The more carefully the examiners are chosen for their human qualities rather than for their academic status, and the more the numbers of the candidates are reduced by preliminary sorting, the fairer will such an examination be.

TRAINING

The training of a surgeon, at any rate of one who is o be more than a journeyman operator, begins after he as taken a higher surgical degree. Knowledge must e increased, wisdom must be acquired, originality must e developed, the ability to speak and write must be earnt by constant practice, and operative experience nd technical skill must be gained by apprenticeship. hese things cannot be found in books. They cannot be elf-taught by the isolated surgeon undertaking responibility without supervision. They can be learnt only y the methods by which every art is learnt, the personal ontact of disciple and teacher. The most important hing therefore in the training of a surgeon is the selection f the man who shall train him. Here again personality s more than ability, the heart is more than the head or he hand. The teacher may not have contributed many dvances to his subject, but originality is a gift that may e discovered but cannot be transmitted; he may be n indifferent operator, but manual skill can be picked p for the watching in any surgical workshop. But if he s able to transmit to his pupils the fire that is in him, o that they think, live, and dream surgery, and turn in heir waking hours to the surgical thoughts on which they have gone to sleep, he will breed a group of young surgeons who will develop the best of which they are capable. And that, after all, must be the aim of training—not to produce men of a certain stamp but to attract the best men to surgery, hand on to them the best we ourselves know, help them to develop the talents that each possesses, and remain prepared to recognise and encourage the best, whatever form it may take and from whatever source it may come. We cannot find the real genius; he will find himself. We cannot do more than start his training, for in the end he will train us.

By planned evolution man has, in the world of plants and animals, produced some striking new forms but ones that have also lost the strength and resilience of their natural stock. By planned education we may lose some essential qualification in striving to develop another. Before the war of 1914–18 the cadet surgeon was given a training that developed his knowledge and teaching ability to the full but did little to train his originality, power of decision, or manual skill. He spent his days teaching in the wards or the dissecting-rooms. He was seldom allowed to operate, and even when he was appointed assistant surgeon he had no beds in his own right. The surgeons trained under this system were fine clinicians and gifted teachers, the writers of excellent textbooks, but they contributed few advances of importance, and they were, on the whole, indifferent operators. The juniors between the two world wars were encouraged to operate at an age and to an extent that were possibly harmful. They did not get enough apprenticeship in bedside discussions or in the basic manœuvres of surgical handicraft. They did not get enough time to think, to read, to watch others at work, to keep themselves in touch with the world outside surgery. They tended to become slick technicians, virtuosos rather than maestros, to be interested in the drama and intricacy of an operation rather than in its purpose, the welfare of an individual patient.

I believe that in the organisation of the surgical services in the recent war we came very near to steering the ideal course between regulated orthodoxy on the one hand and unrestrained empiricism on the other. To those surgeons fortunate enough to be assigned an active rôle in it, the war was the perfect university. They mingled at work and at play with others from every medical school in the English-speaking world. They discussed their problems with men who had faced the same difficulties under different conditions of climate, housing, and supplies. They could seek help from surgeons of greater experience and in turn could sort out their own ideas by helping the newcomer. They were watched, helped, encouraged, guided, restrained, and, if necessary, rested or replaced by consulting surgeons who were watching the whole progress of war surgery over a wider horizon than they could possibly cover. They kept records of their cases, and received reports of the same cases later from other hospitals. They worked in the stress of a forward operating centre during battle and equally hard in the more regulated surgery of a base hospital. They collaborated and argued with experts in every branch of medicine or medical research. They attended conferences. They were inactive for weeks at a time, and if they had used their previous experience well they often learned most in these fallow periods; for it is a peculiarity of the human mind that it is often most fertile in idle periods between spells of hard work. It may thus happen that, while he is watching a chameleon stalking flies in the western desert, or leaning over the rail in some Pacific harbour while the remains of a fleet's breakfast swirls along the ship's side, a surgeon will capture the idea that has eluded him during weeks of intensive study.

INTEGRATION OF KNOWLEDGE

One of the greatest needs of surgery as a whole, as it is for the individual surgeon, is the integration of accumulated knowledge. Intellectual progress, like bodily growth, demands ingestion, digestion, absorption, synthesis, and the elimination of waste products. Many men are spending a forty-hour week on a moderate but secure salary accumulating facts. Many men are describing new signs or symptoms, syndromes or diseases, new instruments or new operations. Very few are attempting to correlate these facts, to sift the corn from the chaff, to take a broad view of the present state of surgery in its relation to medicine as a whole or even to the great body of science, largely because few have the leisure to do so.

Research scholarships and fellowships are now so plentiful that, in many cases, they are no longer a spur to the ambitious and a help to the deserving but a refuge for the timid and a pension for the plodder. Practical benevolence may in the future be more profitably directed to endowing, with the liberality that the position they have secured for themselves warrants and the commit-but we cannot assess mere technique particularly high. Even in plastic surgery, where meticulous artistry might be thought to be the first consideration, the best results are obtained by those who think, plan, and prepare, rather than by those who perform with the self-conscious skill of the trapeze artist. Many of the greatest surgeons were but indifferent operators; and conversely many, perhaps most, brilliant technicians have been second-rate surgeons, earning the meretricious applause of the virtuoso while their artistry was at its heyday—forgotten like the discarded prima donna as soon as their skill passed its zenith.

If we digress from good to bad surgeons, it is difficult to define a bad surgeon more clearly than as one to whom technique is everything, one who has inherited the trends but not the traditions of a great master, who has his mannerisms without his manners. He looks at disease through an endoscope. He speaks of cases not patients. He has no culture, no knowledge of the basic sciences, and therefore no breadth of vision. He knows all about operating except when to refrain.

Probably no surgeon, however great, has possessed all the desirable qualities in their perfection, but those who have become great have possessed many of them in high degree. Greatness of the hand is greatness of the hour, lasting only while the skill lasts and forgotten within a few months of death or retirement. Greatness of the head leads to a secure place during life and an honoured memory afterwards. Greatness of the heart brings a personal influence on patients and pupils and a name that will live among them for one or more generations. When greatness of head and heart are found together they bring immortality; for, though contributions to science and literature become superseded by fresh knowledge, or are merely consulted by the curious as eponyms, such contributions linked to the memory of a human personality and a loved teacher live for all time.

If the ability to found a school in the place where he has worked, and to leave a living memory rather than a bibliography, is the test of greatness, then personality is the most important attribute of the great surgeon. Lawson Tait had an original mind and great operative skill, but he was a boor. Macewen was perhaps the greatest surgical genius of the past 100 years; he had courage in the highest degree, but he lacked generosity and humility; he was admired but not loved and he left few friends and no disciples. Robert Jones, on the other hand, was loved as few surgeons have been loved, and he trained a host of disciples; but he was not outstanding either as an operator or a thinker and, when the present generation of his pupils has passed away, he will be remembered chiefly as the nephew and disciple of Hugh Owen Thomas. John Hunter and, more recently, Rutherford Morison stand out as examples of men who left contributions of lasting importance, the memory of colourful personalities, and successors who carried their names and methods to other years and other lands.

Of Hunter much has been written. His mind wrestled with the whole range of anatomy, physiology, and pathology, often failing because the problems he attacked could not be solved with the methods and instruments of his day, but pointing the solution to those who followed. The fire of his genius threw a beam into the darkness ahead and lit the torch of inquiry that has been the glory of British surgery. His example inspired his contemporaries, and his pupils carried his gospel to all countries.

Rutherford Morison is honoured everywhere in the world, particularly in this place and particularly today. He was great by any definition, because he excelled alike in those qualities of the head, the hand, and particularly of the heart that make for greatness in surgery. He was perhaps fortunate in that, being endowed with a great brain, he was not subjected to any system of education such as we are planning today for the surgeons of the future, designed to mould them to our own conception of the ideal surgeon. He educated himself, and he spent his early years in general practice, where he gained that intimate insight into human nature that was one of his most endearing characteristics. Having entered surgery, he became and remained through life a student of pathology. Of his manual skill many can speak with greater authority than I, but as an operator he was ahead of his time. He will perhaps be remembered best by his operation for ascites and by the right kidney pouch which bears his name, but he was also a pioneer in operations for cancer of the breast, in the dissection of cervical glands, and in gastrectomy. He remained through life a great practical surgeon, careful in undertaking, thorough in performance. Rutherford Morison excelled in qualities of the heart. His teaching was human, vivid, and personal, based on his knowledge and love of the Tynesiders who were his patients and his students. He taught in general principles, which the problem in hand was used to illustrate. And because he was a great man as well as a great surgeon, he handed on the spirit as well as the letter of his creed, and became the greatest disseminator of surgical thought and the greatest maker of surgeons within living memory. Rutherford Morison lives today in two of his greatest pupils, George Grey Turner and Charles Saint, and through them in the surgical departments of the Post-graduate Medical School of London and of the University of Cape Town.

These great surgeons were men of our race. Let us not forget that all the decisive advances in surgery, the application of the scientific method, the development if not the invention of anæsthesia, the demonstration of the cause and prevention of sepsis, the establishment of the technique of asepsis, and finally the discovery and isolation of penicillin, originated in this country, and that British surgery has at all times been and still remains the best in the world.

SELECTION

How can we ensure that this happy state of affairs shall continue? How shall we breed the great surgeons of the future? There are at least four stages in the forming of a surgeon: he must be found, he must be qualified, he must be trained, and he must be given opportunities. If surgery is the high calling we believe it to be, if it deals with problems of the utmost importance in the life of the individual and in the economy of the nation, it must be kept in the hands of worthy men, and worthy men alone. The equality of man is a political belief but not a biological fact, and if we wish our future surgeons to be first-class men we must begin by selecting first-class students to enter surgery.

This selection is made in the English Fellowship, and will shortly be made in the Scottish one, by a preliminary examination. In so far as this acts as a sieve, eliminating the plodders and reducing the entrants for the final examination to numbers that can be assessed thoroughly and fairly, it is good; but in so far as it is vocational in type, and demands not merely a minimum quantity but a certain quality of ability in future surgeons, it is bad. Surgery needs men of every kind—philosophers, dreamers, and poets as well as teachers and men of action—and even the present much improved primary examination sets a premium on a retentive memory and takes little heed of originality.

I reiterate my plea that, though the number of higher examinations should be progressively reduced, thus removing the bar to lateral migration of the gifted from one branch of practice to another along the paths where interest leads and material beckons, there should be a common portal leading to all higher degrees that would

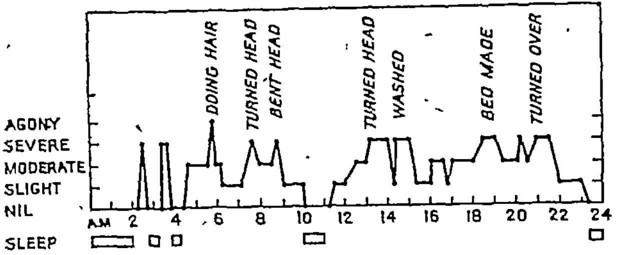

Fig. 4—Chart of pain in region of left trapezius in idiopathic steatorrhœa with tetany (case 4) showing relation of pain to muscular activity.

Though some attacks are typical in their short duration, others last longer and subside leaving hyperalgesia. The patient was intelligent and coöperative but anxious and aware of the diagnosis of "angina." The element of psychogenic overlay in addition to the "organic" pain is present in some attacks. Few cases of angina of effort survive awareness of the diagnosis for many years without this functional overlay.

Case 3.—Fig. 3 shows the relation of epigastric pain to food and alkalis in a patient with gastric ulcer.

USES

The observation of such cases led to the conclusion that this method of charting pain would be capable of revealing more clearly than has yet been possible the intensity curves of pain in ill-understood conditions, such as rheumatoid arthritis, tetany, and carcinomatosis.

Case 4.—Fig. 4 is a pain chart from a woman of 50 with idiopathic steatorrhœa and tetany. Pain was being experienced in many muscles. For the purposes of the chart, observation was limited to pain in the region of the left trapezius. At the time of observation she showed positive Trousseau's and Chvostek's signs. She was a stable and accurate witness.

Though we are told that tetany is a painful condition, it needs the intensity curve of a pain chart to bring full realisation of this. Its close relation to muscular movement is clearly shown.

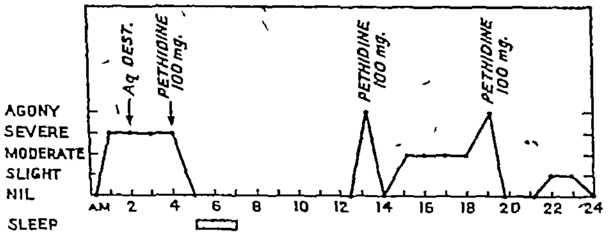

Fig. 5—Chart of organic pain in penis in tuberculous cystitis (case 5) showing response to pethidine intramuscularly but not to distilled water.

These examples illustrate how further knowledge of the intensity of pain can be acquired in various types of cases. By this method relationships between pain and environmental events often emerge more clearly than in the history, and sometimes appear for the first time.

RESPONSE TO ANALGESICS

Another use for the pain chart is in the assessment of response to analgesics.

In the production of pain there are always two elements—the physiological factor of the painful stimulus and its transmission, and the psychogenic factor, which modifies the former in the production of pain. Three broad clinical types of pain can be distinguished: (1) "organic" pain produced by pain stimuli and not modified by suggestion; (2) "psychogenic" pain, which has little or no organic basis and is maximally influenced by suggestion; and (3) "mixed" pain, which combines both elements in various proportions and is the commonest form met with in practice.

It is important to realise that analgesics act by the power of suggestion as well as by their specific analgesic property, and that even in the presence of an apparently sufficient organic cause, such as carcinoma of the stomach, pain may be predominantly psychogenic.

Case 5.—Fig. 5 is part of a pain chart from a man of 37 with bilateral renal tuberculosis and severe tuberculous ulceration of the bladder, who complained of intense recurring pain in the penis, worse on micturition. The absence of response to injection of distilled water is constant in contrast to the effect of pethidine. These observations were repeated several times.

Case 6.—Fig. 6 is part of a pain chart from a man, aged 36, who had undergone splenectomy a year earlier for Banti's disease, partly because of severe pain in the left hypochondrium. He was admitted to hospital with a moderately severe hæmatemesis. Two days later he complained of severe pain in the right hypochondrium, worse on breathing but persistent for long periods. The pain was thought to indicate perihepatitis, and close search was made for a rub, but none was heard. On several occasions response to injection of distilled water was similar to that to pethidine 100 mg. and to morphine gr. $^1/_4$. In all cases it was irregular in duration. Because of this, strong reassurance was given; within a few hours the patient was out of bed, and he has now remained free from pain for ten months.

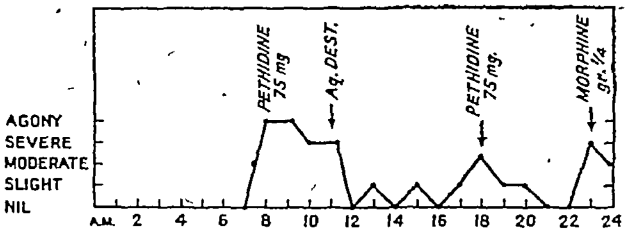

Fig. 6—Chart of psychogenic pain in right hypochondrium in Banti's disease (case 6) showing response to distilled water and irregular response to morphine and pethidine.

This case illustrates the characteristic features of psychogenic pain: (1) irregularity of occurrence, with absence of evidence of organic cause; (2) response on several occasions to a placebo such as distilled water; and (3) irregular response to potent analgesics. Pain charts must be kept for some days to establish these points. In case 6 the chart was largely responsible for converting diagnosis from that of possibly organic pain to that of psychogenic pain.

Case 7.—Fig. 7 is the pain chart from a woman, aged 65, with a fungating carcinoma of the rectum, involving the sacrum, with persistent sacral pain. The effect of the injection of distilled water is comparable with that of morphine. Control of pain depended more on suggestion than on analgesics in this case.

Figs. 5 and 7 are selected from a group of 16 cases of painful organic disease in which assessment of the effect of analgesics was being attempted. It was interesting to observe that 11 of the 16 responded with relief of pain to the administration of distilled water. This was an unexpectedly large proportion and makes clear that in most people the suggestive value of an injection is very real. The specific analgesic property of drugs is reflected only in the pain charts of the remaining 5 cases, one chart of which is shown in fig. 5.

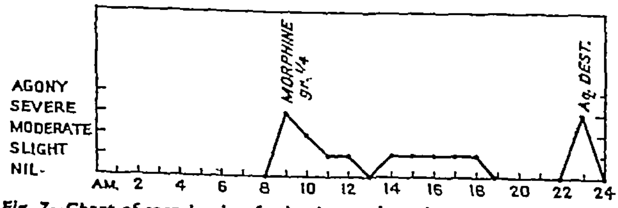

Fig. 7—Chart of sacral pain of mixed organic and psychogenic type in rectal cancer (case 7) showing responses to morphine and to distilled water.

ments they have already undertaken requires, travelling fellowships for successful clinicians between the ages of 40 and 50, so that they may step aside for a year or two from the labour of clinical work and the struggle for economic security and see for a while, as onlookers, the battle in which they have been engaged; so that they may travel and assess the work of their contemporaries in other lands with calmer impartiality and more balanced judgment than the immediate postgraduate can ever do; so that under the stimulus of these fresh contacts they may review the experience of the past ten or fifteen years and attempt to work out the half-formed ideas that have been struggling to find expression.

THE PAIN CHART

K. D. KEELE
M.D. Lond., M.R.C.P.
PHYSICIAN, ASHFORD COUNTY HOSPITAL, MIDDLESEX

THE assessment of pain is of prime importance and necessarily depends on the patient's statement and the observer's judgment. In so far as a method can be devised whereby the inaccuracies involved in a patient's description are reduced to a minimum, an approximation to a "true" description of pain will be obtained.

Sir Thomas Lewis[1] concentrates on qualitative variations and their significance, but considers that "a feature to which too little attention has been given is what may be called the time-intensity curve of pain." This has been my opinion for many years, and the pain chart was designed specifically to meet this requirement and to make the record as accurate as possible. These are but the first steps in rendering pain intelligible to the observer; other factors—e.g., sensitivity to pain—are of obvious importance, but this paper is concerned only with the usefulness of the pain chart.

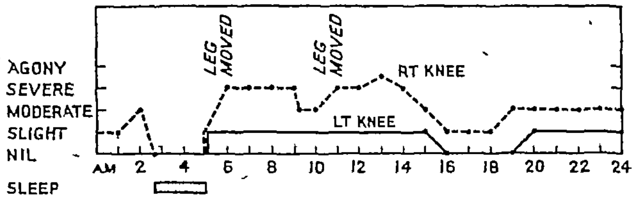

Fig. 1—Chart of pains in right and left knees recorded separately on seventh day after excision of knee-joints for arthritis with deformity (case 1) showing more pain in right knee, in which, unknown to the patient, apposition at operation had been more difficult.

PRINCIPLES

Elimination of Inaccuracies of Description

Inaccuracies of description on the part of the patient arise from three main causes: (1) difficulty in finding words to describe an unusual if not unique experience (Virginia Woolf appreciated this difficulty when she wrote: "let a sufferer try to describe a pain in his head to a doctor, and language runs at once dry"); (2) confusion about what features of this experience are relevant to the observer; and (3) difficulties in remembering the experience.

The pain chart is a time-intensity curve. Qualitative features of pain are therefore ignored. Quantitative assessment of severity is concerned. From this aspect the words chosen spontaneously by patients describing pain were observed, and it was noted that the four words most commonly used in describing degrees of severity were "slight," "moderate," "severe," and "agonising." The following definitions of these terms were reached:

(1) "Slight" pain means awareness of pain without distress.

(2) "Moderate" pain distracts attention from a routine occupation such as reading or housework.

(3) "Severe" pain fills the field of consciousness to the exclusion of other events; visceral reflex accompaniments often occur.

(4) With "agonising" pain motor effects, as evidenced by restlessness, may occur, or the syndrome of "shock" ensue.

These words are explained to the patient and written on a chart for him, thus eliminating his difficulty of choice in words, and confusion about the relevant features.

The Time-intensity Curve

The chart given to the patient is also mapped out into 24 spaces for the hours of the day, and the patient is instructed how to record hourly observation of intensity of pain. If there is a change of intensity this too is to be charted with its time and duration and its relation to any possibly relevant event. Inaccuracies of memory are minimised by almost immediate recording of the pain.

The task is simple, and in almost all cases welcomed by the patient, who after a trial rapidly understands the object of the record. The patient's attempt to grasp the situation often gives information about his intelligence, stability, and coöperation.

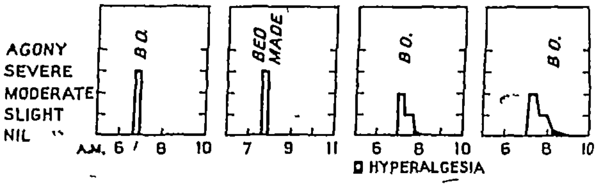

Fig. 2—Chart of substernal pain in angina pectoris (case 2) showing (1) *onset of pain after slight efforts, and* (2) *different types of attack,* some being followed by hyperalgesia. B.O. = Bowels open.

VALIDITY

To test the validity of this method of recording the intensity of pain, cases of pain following known stimuli were selected. The course of postoperative pain is to some extent simple and understood, so charts were made after various operations.

Case 1.—Fig. 1 is a postoperative chart in a case which presented an unusual opportunity for testing the validity of this method, since the operation consisted of excision of both knee-joints for arthritis with deformity. On the left knee the procedure was easy. On the right, considerable difficulty was experienced in obtaining apposition with consequent increase of manipulation. The patient was ignorant of this difference.

The pains in both knees were charted separately on the seventh postoperative day. The increased amount of pain experienced in the right knee as compared with the left is clearly shown by the chart.

Further tests of the method consisted of obtaining charts from cases with typical pain syndromes.

Case 2.—Fig. 2 is the pain chart of a man, aged 65, with *seven years' history of coronary disease with angina of effort* Pain was substernal, radiating to the left arm. The attacks could be *induced by slight effort, including defæcation*

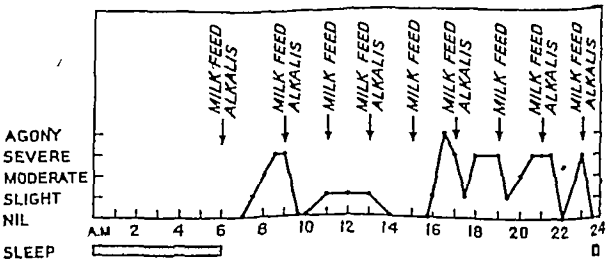

Fig. 3—Chart of epigastric pain in gastric ulcer (case 3) showing relation of pain to food and alkalis.

15	5	tr.	+	7	Normal	15	60
	7	tr.	−	7	Normal	1336	28
16	8	+	+	5	Normal	960	7

mononuclears ranged from 6 to 100%. Segmented and mononuclear cells predominated, with about equal frequency; hence the condition could not justly be ermed a lymphocytic meningitis.

Urine

The urine contained albumin in 10 cases and urobilin in 9. In 6 cases a few erythrocytes, and in 3 cases hyaline casts, appeared temporarily in the sediment. In 7 of the 14 patients we observed a moderate oliguria (less than 1 litre a day with normal fluid intake) lasting from a few days to a week, with poorly concentrated urine (sp. gr.: below 1·015). The chloride content of the urine was low in 5 cases. No bilirubinuria was found.

Blood

In 13 of the 14 patients the blood-urea level remained from slightly to moderately high (600–1400 mg. per litre) for one to three weeks:

1400 mg. litre in 1 patient	700 mg. litre in 2 patients
1150 ,, ,, 1 ,,	650 ,, ,, 2 ,,
900 ,, ,, 1 ,,	600 ,, ,, 3 ,,
750 ,, 3 patients	

A slightly raised value for the van den Bergh indirect reaction was found in 4 patients only (1·0, 1·4, 1·2, and 1·2 units). Possibly we might have obtained more pathological readings if we had done the tests at an earlier stage. In many cases, however, it was not until the disease was far advanced that we were led to suspect leptospirosis. Since we have adopted the routine of testing the blood of all patients with serous meningitis for bile pigments, even when there is no question of leptospirosis, we have found increased values in many cases; this applies also to blood-urea. Thus high values for the van den Bergh reaction and the blood-urea level do not help in the differential diagnosis of the various forms of serous meningitis.

In most cases we found the chloride content of the serum to be lowered:

345–385 mg. per 100 ml.	8 patients
400 ,, ,, ,, ...	2 ,,
533–562 ,, ,, ,, ...	2 ,,
540–585 ,, ,, ,, ...	2 ,,

The erythrocyte-sedimentation rate (E.S.R.) remained high to very high for a considerable time (14–109 days after admission to hospital):

E.S.R. on admission (mm. in 1 hr.)..	68	72	60	65	100	48	42	25	72	40	22	17	94	86
Days to become normal	1	41	37	37	109	71	34	30	72	14	14	60	90	28

The white-cell counts ranged from 6100 to 16,000 per c.mm. There was a pronounced shift to the left in 4 cases, and lymphopenia in 3. The eosinophils in the 14 cases were 0% in 9 cases, 3% in 1 case, 4% in 3 cases, and 12% in 1 case.

Liver

Owing to shortage of staff it was impossible to carry out liver-function tests on all the patients; in some cases where such tests were made they revealed distinct functional disturbance.

Relapses

In 4 cases there were relapses (on the 14th–17th day) which lengthened the illness by 12–33 days.

d.-c.=direct culture; g.-p.=guineapig.

Though the suggestive effects of all modes of treatment are recognised to be important, there has been a remarkable tendency to ignore this factor in assessing the many medical or surgical pain-relieving procedures designed in the past. Any procedure with a high suggestive content will probably have some success in over 50% of cases, regardless of any specific interference with the physiology of the pain. This needs to be borne in mind particularly when considering the benefits of operation for anginal pain or the pain of peptic ulcer.

SUMMARY

A simple method of minimising errors of description by standardising terminology, and recording intensity of pain in a pain chart, is described.

The validity of the chart has been assessed by observation of pain following surgical operations, and typical clinical pain syndromes such as angina of effort and gastric ulcer.

Pain charts are of value in defining the action of analgesics.

"Psychogenic" and "organic" pain can thus be differentiated.

Even in the presence of organic disease the psychogenic factor of pain is important, and its share in any response to medical or surgical pain-relieving procedures can often be assessed by the use of pain charts.

I wish to thank the ward sisters and nurses of the Royal Northern Hospital, St. Bartholomew's Hospital, and Ashford County Hospital, where this work was done.

LEPTOSPIROSIS CANICOLARIS

J. E. MINKENHOF

PHYSICIAN TO THE DEPARTMENT FOR INFECTIOUS DISEASES,
WILHELMINA HOSPITAL, AMSTERDAM

Leptospira canicola, discovered in 1931 by Klarenbeek and Schüffner,[12] belongs to a serologically well-defined leptospira type[38] which appears to affect mainly man and the dog. For guineapigs this micro-organism is usually less virulent than *L. icterohæmorrhagiæ*, but *L. canicola* produces a fatal infection in hamsters (*Cricetus auratus*). Other animals used for laboratory tests—e.g., mice and albino, brown, and black rats—remain practically unaffected by *L. canicola*.

An investigation into the extent of infection in dogs [6 17 21 23 26 29 31–34 37] was carried out in various parts of the world with the aid of agglutination and lysis reactions of dog sera with *L. canicola*. The results ranged from 0·6 to 90%.

In dogs, usually males, the disease, which is probably identical with the Stuttgarter Hundeseuche described by Klett and with typhus canum, may run a mild course but is often serious and sometimes fatal. In many of the affected dogs acute or chronic azotæmic or uræmic signs predominate[11 14]; in others ulcerative stomatitis and hæmorrhagic gastro-enteritis are the most striking features, while in some cases jaundice is observed.[8 36] In animals which survive the disease leptospiruria persists for several months; this is easily detected if a drop of freshly voided urine is examined with dark-field illumination. If the urine is acid the organisms soon die.

INCIDENCE IN MAN

Though it appears probable that in many parts of the world most dogs become infected with *L. canicola* and remain infectious for a considerable time, only a few score of cases in human beings have been reported [1–4 7 9 10 13 16 18 22 23 25 28 30 36]:

Country	*Cases*	*Country*	*Cases*
Austria	1	France	5
Germany	1	U.S.A.	7
Switzerland	18	Argentine	1
Denmark	21	China	2
Norway	1	Netherlands	40
England	1		

In the Institute of Tropical Hygiene in Amsterdam 49 human cases of this disease were diagnosed between 1933 and the autumn of 1947 (6 with jaundice; 1 fatal). We have observed 17 of these patients in the Wilhelmina Hospital in Amsterdam (14 as inpatients, 3 as outpatients) in sixteen months starting in the autumn of 1946. (1 in July, 2 in August, 5 in September, 4 in October, and 5 in November.) Our experience at that time caused us to wonder whether we were justified in continuing to regard febris canicolaris as the rare zoonosis which it was generally assumed to be. It seemed probable that further investigation would reveal considerably more cases in man.

SIGNS AND SYMPTOMS

On admission to hospital (in both years only between July and December) these patients were suspected to have epidemic cerebrospinal meningitis, infantile paralysis, or typhoid fever.

Onset

The onset was usually acute, with high temperature, shivering, vomiting, severe headache, dizziness, and *muscular pain which in a few exceptional cases was* practically confined to the calves. Some patients complained of sore throat and obstinate constipation. About half of them had suffered from disturbed sleep and impairment of consciousness, and were described by their relations as having been peculiarly irritable. The clinical data at onset were as follows:

Acute onset	13 cases	Muscular pain (chiefly in calves)	3 cases
Fever	17 „	Stitch in the side	2 „
Shivering	10 „	Lumbar pain	4 „
Vomiting	12 „	Constipation	7 „
Headache	16 „	Nose-bleeding	2 „
Dizziness	10 „	Disturbed sleep	18 „
Sore throat	5 „	Drowsiness	6 „
Pain in joints	5 „	Stiff neck	7 „
Muscular pain (generalised)	11 „	Irritability	9 „

Course

The duration of pyrexia ranged from two to forty-eight days, excluding relapses. The other signs observed during their stay in hospital were as follows:

Seriously ill	15	Lowered blood-pressure	7
Drowsy	7	Slight pulse-pressure	5
Jaundice	0	Exanthema	0
General swelling of glands	5	Hæmorrhages	0
Relative retardation of pulse	9	Injected conjunctiva	4
Herpes labialis	1	Meningeal irritation after admission to hospital:	
Coated tongue	7	lasting 9 days .. 6	
Spleen palpable	0	„ 11 „ .. 4	
Liver palpable	2	„ 12 „ .. 2	
Reflex abnormalities	0	„ 17 „ .. 1	13

No jaundice was observed in these patients; no enlargement of liver or spleen could be felt; and the conjunctiva was injected in only 4 patients. In the 14 inpatients a temporary fall in blood-pressure was observed seven times in the course of one or two weeks, and on five occasions the pulse-pressure was notably low.

Cerebrospinal Fluid

All the inpatients but one showed signs of meningeal irritation nine to seventeen days after admission. In the cerebrospinal fluid (table I) the protein content was increased in all cases (Nonne reaction positive; Pandy reaction positive, except in case 6, with 8–4% solutions of phenol). The sugar content was normal, slightly high, or slightly low; in no case was the Fehling reaction negative, so the value was certainly above 35 mg. per 100 ml. The number of cells varied from 12 to 2450 per c.mm. according to the day of the illness on which the count was made (the number of cells increased in the second week of illness), and the proportion of

TABLE I—FINDINGS IN CEREBROSPINAL FLUID IN 14 HUMAN CASES OF LEPTOSPIROSIS CANICOLARIS

mononuclears ranged from 6 to 100%. Segmented and mononuclear cells predominated, with about equal frequency; hence the condition could not justly be termed a lymphocytic meningitis.

Urine

The urine contained albumin in 10 cases and urobilin in 9. In 6 cases a few erythrocytes, and in 3 cases hyaline casts, appeared temporarily in the sediment. In 7 of the 14 patients we observed a moderate oliguria (less than 1 litre a day with normal fluid intake) lasting from a few days to a week, with poorly concentrated urine (sp. gr.: below 1·015). The chloride content of the urine was low in 5 cases. No bilirubinuria was found.

Blood

In 13 of the 14 patients the blood-urea level remained from slightly to moderately high (600–1400 mg. per litre) for one to three weeks:

1400 mg./litre in 1 patient	700 mg./litre in 2 patients
1150 ,, ,, 1 ,,	650 ,, ,, 2 ,,
900 ,, ,, 1 ,,	600 ,, ,, 3 ,,
750 ,, ,, 3 patients	

A slightly raised value for the van den Bergh indirect reaction was found in 4 patients only (1·0, 1·4, 1·2, and 1·2 units). Possibly we might have obtained more pathological readings if we had done the tests at an earlier stage. In many cases, however, it was not until the disease was far advanced that we were led to suspect leptospirosis. Since we have adopted the routine of testing the blood of all patients with serous meningitis for bile pigments, even when there is no question of leptospirosis, we have found increased values in many cases; this applies also to blood-urea. Thus high values for the van den Bergh reaction and the blood-urea level do not help in the differential diagnosis of the various forms of serous meningitis.

In most cases we found the chloride content of the serum to be lowered:

345–385 mg. per 100 ml.	8 patients
400 ,, ,, ,, ...	2 ,,
533–562 ,, ,, ,, ...	2 ,,
540–585 ,, ,, ,, ...	2 ,,

The erythrocyte-sedimentation rate (E.S.R.) remained high to very high for a considerable time (14–109 days after admission to hospital):

E.S.R. on admission (mm. in 1 hr.) ..	68	72	60	65	100	48	42	25	72	40	22	17	94	86
Days to become normal	?	41	37	37	109	71	34	30	73	14	14	60	90	28

The white-cell counts ranged from 6100 to 16,000 per c.mm. There was a pronounced shift to the left in 4 cases, and lymphopenia in 3. The eosinophils in the 14 cases were 0% in 9 cases, 3% in 1 case, 4% in 3 cases, and 12% in 1 case.

Liver

Owing to shortage of staff it was impossible to carry out liver-function tests on all the patients; in some cases where such tests were made they revealed distinct functional disturbance.

Relapses

In 4 cases there were relapses (on the 14th–17th day) which lengthened the illness by 12–33 days.

TREATMENT AND PROGRESS

Treatment was symptomatic. Penicillin was at that time in short supply, so we did not feel justified in using it, though it has been shown by tests on animals and in vitro to be active against *L. canicola* [29, 27, 30] and has been recommended by Baber and Stuart [2] for human cases.

Many of the patients in the series recovered extremely slowly ; some of them did not feel well for many weeks or even months. The serious complications that have been reported,[5] such as myocarditis, uræmia, and paralysis, were not seen in this group, and only 1 patient developed pneumonia.

In 1 case the leptospirosis ran such a mild course as almost to deserve the designation *infection inapparente.* The patient merely felt slightly unwell for two days.

BACTERIOLOGICAL AND SEROLOGICAL TESTS

Table II shows the results of laboratory tests in all the cases. Attempts to culture leptospira directly from the blood and cerebrospinal fluid of the patients were made in only a few cases, because in several cases there were few if any grounds for suspecting leptospirosis in the beginning, and in others the disease was too far advanced by the time they were admitted to hospital. A further difficulty was the great shortage of guineapigs of suitable weight (150–200 g.).

The rise in titre of the sera with canicola strains was sometimes perceptible in the second week but often not until the fourth week of the illness or later. The classical Weil strains usually showed a high degree of co-agglutination, especially with antigen A ; this was most pronounced during the first weeks of the illness. In some cases it was found necessary to confirm the diagnosis by a Ruys and Schüffner absorption test.[24] The strain, *L. ballum,* cultured in 1941 by Schüffner from an albino mouse and in 1944 by Petersen [10] from *Mus musculus spicilegus,* often showed distinct co-agglutination with the sera from the canicola patients, though this was seldom observed with sera from patients with Weil's disease. The strains *L. pomona, L. sejroe,* and *L. grippo-typhosa* showed little or no agglutination.

TABLE III—FINDINGS IN DOGS WHICH INFECTED HUMAN PATIENTS

In case 8 the dog was not examined.

DIFFERENTIAL DIAGNOSIS

Leptospirosis canicolaris cannot be diagnosed without bacteriological or serological tests. As a rule, differential diagnosis by clinical means from poliomyelitis without paralysis, from meningitis due to mumps without any affection of the glands, and from Armstrong's lymphocytic meningitis—to mention only a few examples—is impossible. The complement-fixation test with mumps antigen is not decisive until the convalescent phase has been reached, and the effect of cerebrospinal fluid injected intracerebrally into mice requires ten to fourteen days for confirmation—or the reverse—of a diagnosis of lymphocytic meningitis.

The most we can do clinically is to suspect leptospirosis. If the patient has been ill for less than eight days there is a fair chance of cultivating leptospira in the guineapig or hamster or on Vervoort's medium within a further three to seven days, after which the type can be determined serologically. For this purpose 4·5 ml. of blood should be used, mixed with 0·5 ml. of 1% sterile sodium oxalate solution buffered to pH 8. If the patient has been ill for longer than eight days it will be necessary to wait until the 10th–14th day before agglutinins and lysins for leptospira can be expected to be detectable. In many cases several weeks elapse before it is possible to decide for which leptospira type the patient possesses the most antibodies. Thus, as a rule, the diagnosis cannot be established until convalescence is far advanced, and then only with the assistance of a skilled bacteriologist with special equipment. From the clinical point of view all forms of leptospirosis (Weil's disease, canicola fever, swineherd's or pomona fever, mud fever, rice-field fever, Batavia fever, &c.) run a precisely similar course.

SOURCE OF INFECTION

In 23 of the 49 cases recognised in Amsterdam the dog responsible for transmitting the infection was traced ; these cases included 14 of the 17 discussed here. The results of examination of these dogs are given in table III. In connexion with cases 6, 7, 8, and 10 it was found that a bitch and her six puppies were all infected. We observed leptospira in the urine of these animals for many weeks. At least one of them died. (In 19 human contacts of this canine family, not mentioned above, no agglutinins or lysins against *L. canicola* could be found.) Unfortunately we were not in a position to ascertain whether the serum of these dogs contained antibodies causing agglutination or lysis of *L. ballum.*

Experiments on a restricted scale were made with one dog in the hope of ascertaining the effect of penicillin on the leptospiruria. After 25,000 units twice daily on two successive days the leptospiræ in the urine were temporarily much reduced in number and agglutinated spontaneously.

SUMMARY

At the Institute of Tropical Hygiene in Amsterdam 49 cases of febris canicolaris have been diagnosed since 1933 (6 with jaundice, 1 ending fatally).

The symptoms and bacteriological and serological data of 17 cases observed from the summer of 1946 to the autumn of 1947 in the Wilhelmina Hospital in Amsterdam are described.

In 14 cases of this group the sources of infection were traced by means of bacteriological and serological examination of the urine and serum of canine contacts.

The laboratory tests from which table II is compiled were done by Miss H. Bohlander at the Institute of Tropical Hygiene, Amsterdam.

MALARIAL DIABETES

REPORT OF A CASE

LEO RAU
M.R.C.P.

It has long been known that malaria produces different clinical syndromes according to its incidence in different organs—e.g., cerebral malaria, malarial dysentery, &c. Manson-Bahr (1946) mentions acute hæmorrhagic pancreatitis caused by a blockage of capillaries by *Plasmodium falciparum*. Cerebral malaria is sometimes wrongly diagnosed as heat-stroke, sun-stroke, heat-exhaustion, and often ends in fatal coma, and the true diagnosis is established by the discovery of malarial parasites in the blood capillaries. On the other hand, latent malarial infection without clinical symptoms of sufficient gravity to attract attention is often missed. In the following case the latent malaria seemed at first to be of no clinical significance.

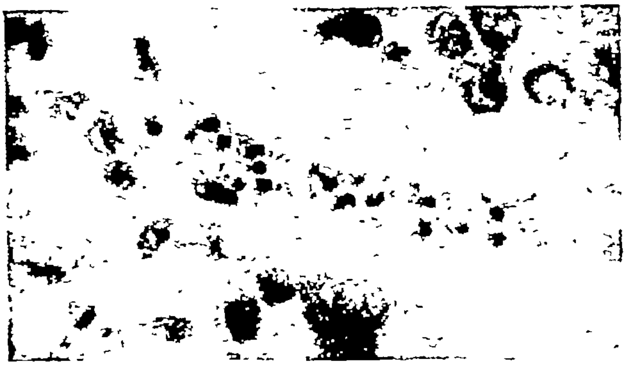
A married man, aged 43, returned from India in June, 1947, after six years there. In the middle of July he noticed frequency of micturition and excessive thirst, and he found his weight had fallen from 13st. 11 lb. to 10 st. 13 lb. There was no pyrexia at this time. The only disease of significance in his past history was malaria, which he had had at the age of 19. In January, 1947, he had had an attack of difficulty in breathing. He was a member of a large family in which neither hereditary nor any other disease had been noted.

On examination on Aug. 21 his temperature was normal, pulse-rate 66 per min., and blood-pressure 110/70 mm. Hg. The patient appeared ill but not pale. There was no cyanosis, no dyspnœa, and no jaundice of skin or mucosæ. The pupils reacted to light and accommodation, the fundi and ocular movements were normal. The tongue was moist, not furred. Nothing abnormal was detected in his abdomen; spleen and liver were not felt. Central nervous system normal. Urine: sp. gr. 1·030, no albumin, sugar ++, no acetone, no diacetic acid. Blood film: ring forms of malignant tertian (M.T.) malaria present. Next day his fasting blood-sugar was 350 mg. per 100 ml. On the 24th he became worse. Urine: sugar +++, acetone ++, diacetic acid ++. Fasting blood-sugar 350 mg. per 100 ml. He had a headache and felt drowsy and sleepy. He could not walk unaided. Treatment with insulin (30 units three times daily) and a diet of 2500 calories was begun. On the 25th his fasting blood-sugar had dropped to 182 mg. per 100 ml. and on the 28th he was much improved. Urine: sugar trace. Fasting blood-sugar 170 mg. per 100 ml.

During the next two weeks the patient remained fairly well His urine was free from sugar, but his fasting blood-sugar level was still raised.

On Sept. 12 his condition was still satisfactory. The insulin had been reduced to 30 units twice daily, leading to the reappearance of sugar in the urine. On this day he was given 'Paludrine' 0·1 g. twice daily for ten days. On the 22nd the urine was sugar-free although the diet was unchanged at 2500 calories a day, and the insulin dosage was still 30 units a day.

On Oct. 9 the urine remained sugar-free, and the fasting blood-sugar was 104 mg. per 100 ml. On Oct. 31 he was no longer on a restricted diet and was not receiving any insulin. During the next three months his urine on weekly examination was always sugar-free.



Section of pancreas through islets of Langerhans showing a blood-vessel blocked by red blood-cells containing malarial pigment. (× 900.)

On Feb. 18, 1948, the sugar-tolerance test after 50 g. of glucose was as follows:

	Fasting	*45 min.*	*90 min.*	*150 min.*
Blood-sugar (mg. per 100 ml.)	93	104	120	86

Urine sugar-free throughout.

COMMENT

There is reason to believe that this glycosuria was caused by a pathological condition of the islets of Langerhans. All tests and the response to insulin and diet confirm this.

Renal glycosuria and diabetes occur in tropical countries, but de Langen and Lichtenstein (1936) remark that "Glycosuria in the tropics is never caused by malaria, and diabetes is a rare disease, occurring in 1 : 11,000 patients only." Ash and Spitz (1945) do not mention any abnormality of the pancreas in malaria. Seyfarth (1926) and Gruber (1929) emphasise the possibility of malaria in the islets of Langerhans and suggest it as a possible cause of diabetes.

In the present case the diabetes was evidently caused by M.T. malaria of the islets of Langerhans, and was apparently cured by specific antimalarial treatment. Prof. R. J. V. Pulvertaft, with whom I discussed this case, showed me sections of islets of Langerhans in which the capillaries were completely blocked by red blood corpuscles loaded with M.T. plasmodia. These sections were obtained for the following cases, observed by Professor Pulvertaft:

The first case which came to his notice was that of a flight-lieutenant who was admitted to a Service hospital in Cairo immediately after arriving from West Africa by air. He complained of vague malaise, was foolish in his manner, and did not seem to know where he was. He was thought to be suffering from the effects of some drug. During his first night in hospital he was found dead. Necropsy revealed an enormous spleen, and all the organs were full of parasites

TREATMENT AND PROGRESS

Treatment was symptomatic. Penicillin was at that time in short supply, so we did not feel justified in using it, though it has been shown by tests on animals and in vitro to be active against *L. canicola* [20 27 39] and has been recommended by Baber and Stuart [2] for human cases.

Many of the patients in the series recovered extremely slowly; some of them did not feel well for many weeks or even months. The serious complications that have been reported,[5] such as myocarditis, uræmia, and paralysis, were not seen in this group, and only 1 patient developed pneumonia.

In 1 case the leptospirosis ran such a mild course as almost to deserve the designation *infection inapparente.* The patient merely felt slightly unwell for two days.

BACTERIOLOGICAL AND SEROLOGICAL TESTS

Table II shows the results of laboratory tests in all the cases. Attempts to culture leptospira directly from the blood and cerebrospinal fluid of the patients were made in only a few cases, because in several cases there were few if any grounds for suspecting leptospirosis in the beginning, and in others the disease was too far advanced by the time they were admitted to hospital. A further difficulty was the great shortage of guineapigs of suitable weight (150–200 g.).

The rise in titre of the sera with canicola strains was sometimes perceptible in the second week but often not until the fourth week of the illness or later. The classical Weil strains usually showed a high degree of co-agglutination, especially with antigen A; this was most pronounced during the first weeks of the illness. In some cases it was found necessary to confirm the diagnosis by a Ruys and Schüffner absorption test.[24] The strain, *L. ballum*, cultured in 1941 by Schüffner from an albino mouse and in 1944 by Petersen [19] from *Mus musculus spicilegus*, often showed distinct co-agglutination with the sera from the canicola patients, though this was seldom observed with sera from patients with Weil's disease. The strains *L. pomona*, *L. sejroe*, and *L. grippo-typhosa* showed little or no agglutination.

DIFFERENTIAL DIAGNOSIS

Leptospirosis canicolaris cannot be diagnosed without bacteriological or serological tests. As a rule, differential diagnosis by clinical means from poliomyelitis without paralysis, from meningitis due to mumps without any affection of the glands, and from Armstrong's lymphocytic meningitis—to mention only a few examples—is impossible. The complement-fixation test with mumps antigen is not decisive until the convalescent phase has been reached, and the effect of cerebrospinal fluid injected intracerebrally into mice requires ten to fourteen days for confirmation—or the reverse—of a diagnosis of lymphocytic meningitis.

The most we can do clinically is to suspect leptospirosis. If the patient has been ill for less than eight days there is a fair chance of cultivating leptospira in the guineapig or hamster or on Vervoort's medium within a further three to seven days, after which the type can be determined serologically. For this purpose 4·5 ml. of blood should be used, mixed with 0·5 ml. of 1% sterile sodium oxalate solution buffered to pH 8. If the patient has been ill for longer than eight days it will be necessary to wait until the 10th–14th day before agglutinins and lysins for leptospira can be expected to be detectable. In many cases several weeks elapse before it is possible to decide for which leptospira type the patient possesses the most antibodies. Thus, as a rule, the diagnosis cannot be established until convalescence is far advanced, and then only with the assistance of a skilled bacteriologist with special equipment. From the clinical point of view all forms of leptospirosis (Weil's disease, canicola fever, swineherd's or pomona fever, mud fever, rice-field fever, Batavia fever, &c.) run a precisely similar course.

SOURCE OF INFECTION

In 23 of the 49 cases recognised in Amsterdam the dog responsible for transmitting the infection was traced; these cases included 14 of the 17 discussed here. The results of examination of these dogs are given in table III. In connexion with cases 6, 7, 8, and 10 it was found that a bitch and her six puppies were all infected. We observed leptospira in the urine of these animals for many weeks. At least one of them died. (In 19 human contacts of this canine family, not mentioned above, no agglutinins or lysins against *L. canicola* could be found.) Unfortunately we were not in a position to ascertain whether the serum of these dogs contained antibodies causing agglutination or lysis of *L. ballum*.

Experiments on a restricted scale were made with one dog in the hope of ascertaining the effect of penicillin on the leptospiruria. After 25,000 units twice daily on two successive days the leptospiræ in the urine were temporarily much reduced in number and agglutinated spontaneously.

SUMMARY

At the Institute of Tropical Hygiene in Amsterdam 49 cases of febris canicolaris have been diagnosed since 1933 (6 with jaundice, 1 ending fatally).

The symptoms and bacteriological and serological data of 17 cases observed from the summer of 1946 to the autumn of 1947 in the Wilhelmina Hospital in Amsterdam are described.

In 14 cases of this group the sources of infection were traced by means of bacteriological and serological examination of the urine and serum of canine contacts.

The laboratory tests from which table II is compiled were done by Miss H. Bohlander at the Institute of Tropical Hygiene, Amsterdam.

MALARIAL DIABETES

REPORT OF A CASE

LEO RAU
M.R.C.P.

It has long been known that malaria produces different clinical syndromes according to its incidence in different organs—e.g., cerebral malaria, malarial dysentery, &c. Manson-Bahr (1946) mentions acute hæmorrhagic pancreatitis caused by a blockage of capillaries by *Plasmodium falciparum*. Cerebral malaria is sometimes wrongly diagnosed as heat-stroke, sun-stroke, heat-exhaustion, and often ends in fatal coma, and the true diagnosis is established by the discovery of malarial parasites in the blood capillaries. On the other hand, latent malarial infection without clinical symptoms of sufficient gravity to attract attention is often missed. In the following case the latent malaria seemed at first to be of no clinical significance.

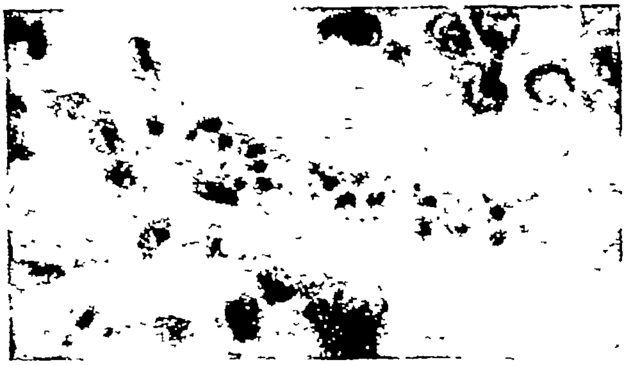
A married man, aged 43, returned from India in June, 1947, after six years there. In the middle of July he noticed frequency of micturition and excessive thirst, and he found his weight had fallen from 13st. 11 lb. to 10 st. 13 lb. There was no pyrexia at this time. The only disease of significance in his past history was malaria, which he had had at the age of 19. In January, 1947, he had had an attack of difficulty in breathing. He was a member of a large family in which neither hereditary nor any other disease had been noted.

On examination on Aug. 21 his temperature was normal, pulse-rate 66 per min., and blood-pressure 110/70 mm. Hg. The patient appeared ill but not pale. There was no cyanosis, no dyspnœa, and no jaundice of skin or mucosæ. The pupils reacted to light and accommodation, the fundi and ocular movements were normal. The tongue was moist, not furred. Nothing abnormal was detected in his abdomen; spleen and liver were not felt. Central nervous system normal. Urine: sp. gr. 1·030, no albumin, sugar ++, no acetone, no diacetic acid. Blood film: ring forms of malignant tertian (M.T.) malaria present. Next day his fasting blood-sugar was 350 mg. per 100 ml. On the 24th he became worse. Urine: sugar +++, acetone ++, diacetic acid ++. Fasting blood-sugar 350 mg. per 100 ml. He had a headache and felt drowsy and sleepy. He could not walk unaided. Treatment with insulin (30 units three times daily) and a diet of 2500 calories was begun. On the 25th his fasting blood-sugar had dropped to 182 mg. per 100 ml. and on the 28th he was much improved. Urine: sugar trace. Fasting blood-sugar 170 mg. per 100 ml.

During the next two weeks the patient remained fairly well His urine was free from sugar, but his fasting blood-sugar level was still raised.

On Sept. 12 his condition was still satisfactory. The insulin had been reduced to 30 units twice daily, leading to the reappearance of sugar in the urine. On this day he was given 'Paludrine' 0·1 g. twice daily for ten days. On the 22nd the urine was sugar-free although the diet was unchanged at 2500 calories a day, and the insulin dosage was still 30 units a day.

On Oct. 9 the urine remained sugar-free, and the fasting blood-sugar was 104 mg. per 100 ml. On Oct. 31 he was no longer on a restricted diet and was not receiving any insulin. During the next three months his urine on weekly examination was always sugar-free.



Section of pancreas through Islets of Langerhans showing a blood-vessel blocked by red blood-cells containing malarial pigment. (× 900.)

On Feb. 18, 1948, the sugar-tolerance test after 50 g. of glucose was as follows:

	Fasting	*45 min.*	*90 min.*	*150 min.*
Blood-sugar (mg. per 100 ml.)	93	104	120	86

Urine sugar free throughout.

COMMENT

There is reason to believe that this glycosuria was caused by a pathological condition of the islets of Langerhans. All tests and the response to insulin and diet confirm this.

Renal glycosuria and diabetes occur in tropical countries, but de Langen and Lichtenstein (1936) remark that "Glycosuria in the tropics is never caused by malaria, and diabetes is a rare disease, occurring in 1 : 11,000 patients only." Ash and Spitz (1945) do not mention any abnormality of the pancreas in malaria. Seyfarth (1926) and Gruber (1929) emphasise the possibility of malaria in the islets of Langerhans and suggest it as a possible cause of diabetes.

In the present case the diabetes was evidently caused by M.T. malaria of the islets of Langerhans, and was apparently cured by specific antimalarial treatment. Prof. R. J. V. Pulvertaft, with whom I discussed this case, showed me sections of islets of Langerhans in which the capillaries were completely blocked by red blood corpuscles loaded with M.T. plasmodia. These sections were obtained for the following cases, observed by Professor Pulvertaft:

The first case which came to his notice was that of a flight-lieutenant who was admitted to a Service hospital in Cairo immediately after arriving from West Africa by air. He complained of vague malaise, was foolish in his manner, and did not seem to know where he was. He was thought to be suffering from the effects of some drug. During his first night in hospital he was found dead. Necropsy revealed an enormous spleen, and all the organs were full of parasites

DISCUSSION

These are the third and fourth recorded cases of a typical pilonidal sinus in a barber's hand, and it seems impossible to avoid the conclusion that the pilonidal sinus was an acquired condition and due to the penetration of hair clippings. A similar mechanism of origin must therefore be admitted as a possibility in the postanal region. If pilonidal sinus is an acquired infective condition, there are two phases in its development: (1) an initial phase in which organisms are introduced into the tissues, there to give rise to the infection leading to the sinus; and (2) the entrance of hairs into the sinus to produce the foreign-body granulomatous reaction. Subsequent epithelisation of the sinus from the surface in part or in whole may or may not take place, and the same applies to secondary abscess and sinus formation. In the case of the barber's hands hair seems to be concerned with both phases of development.

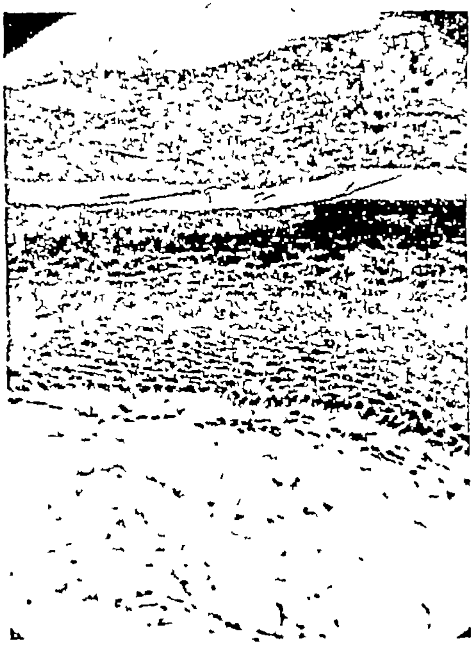

Fig. 3—Squamous lining of pilonidal sinus. (×200.)

But pilonidal sinus—i.e., a foreign-body granuloma round hair—may still develop even if the original mechanism of introduction of infection is not penetration by a hair. In the postanal region, for example, the infection often seems to start at the base of a hair follicle. The main fact requiring explanation on the acquired theory of pilonidal sinus is why hairs tend to enter sinuses substantially in two situations only—the web of the fingers, and the upper end of the postanal cleft. Such an explanation is particularly necessary for the postanal region, because only a short distance away anal and ischiorectal sinuses show no tendency to become pilonidal.

A possible explanation is that the hairs enter the sinus not by being pushed in but by being sucked in. If a simple experiment is made with a rubber bulb with a narrow orifice, it will not be found easy to introduce a long soft hair into the bulb by pushing the hair; but, if after the hair has been partly introduced, a sudden negative pressure is created in the bulb, the hair tends to be sucked in with great ease. We therefore suggest that the reason why sinuses in the webs of the fingers and near the postanal cleft tend to become pilonidal is that in these regions negative pressures are readily produced: in the webs of the fingers by the alternating tautening and loosening of the tissues during movements of the fingers; and near the postanal cleft by the alternating pressure and relaxation of the soft tissues against the coccyx and sacrum during sitting. It was a current idea in the American army that driving for a long time in motor vehicles with hard seats predisposed to pilonidal sinus, and a popular name for the condition was "jeep disease."

As regards treatment we suggested in our previous article[1] that operation in a field made hairless by irradiation should help to prevent recurrence. Further, if our present view is correct, an essential principle of surgical technique should be to secure adhesion of the skin and subcutaneous tissue flaps to the deep fascia so as to avoid a sucking wound. And this principle should apply whether the wound is allowed to granulate and epithelise secondarily or whether one of the many techniques aiming at primary union is used.

Medical Societies

BRITISH ASSOCIATION OF UROLOGICAL SURGEONS

THE annual meeting was held in London on June 24, 25, and 26.

Surgery of Urethral Stricture

In opening the discussion on June 24, with Mr. WALTER GALBRAITH, president of the section of urology of the Royal Society of Medicine, in the chair, Mr. H. L. ATTWATER remarked that urethral strictures were becoming less common, and he emphasised their very slow and insidious development. Only 5% occur within 5 years of the original infection and the average latent interval is 25½ years. Dilatation as a method of treatment has been tried for at least 3000 years. In applying it two important principles must be observed—extreme gentleness in instrumentation and regular repetition of the treatment for the rest of the patient's life—"*once a stricture, always a stricture.*" But dilatation *is not* always successful. Failure may be due to extreme density of the stricture, acute sepsis, calculi, irritable stricture, and the inability of the patient to stand the discomfort or pain of repeated dilatation. Resilient stricture is rare, and its appearances are often caused by muscular spasm; such cases are best treated by continuous dilatation. Impassable and impermeable strictures are a definite indication for surgical measures. In acute retention it is important to use very little urethral instrumentation since severe reactions and uræmia are easily caused. A suprapubic cystostomy should be done judiciously soon.

Traumatic lesions of the urethra are of three main types—those due to direct wounding, those due to perineal bruising (as in falling astride), and those associated with fractured pelvis. In the immediate treatment of these injuries it is permissible to attempt catheterisation very gently. If this fails it is often necessary to drain the bladder suprapubically and leave the local treatment of the injury until later, because of the severe shock often present. But in rupture of the urethra with fractured pelvis an immediate repair is necessary to avoid the development of a serious obstruction which it would be very difficult to put right. If delayed operation becomes necessary for any of these types of case it is important to wait until all local complications and sepsis are over. A preliminary intravenous pyelogram may be very helpful in showing the exact site and form of the lesion. A new type of traumatic stricture is that due to endoscopic prostatic surgery. It has been calculated that in an average resection the instrument is moved 800 times in the urethra and it is therefore obvious what chances there are for injury. For the stricture due to chronic prostatitis dilatation is often satisfactory but the retropubic approach may be a new answer to this problem as it has been to that of postprostatectomy stricture.

In the female urethral stricture is commoner than is generally supposed and it is a serious condition. This would be expected, for in the male a stricture becomes progressively more serious as its site approaches the bladder, and the female urethra corresponds with the posterior urethra of the male.

When local infective complications arise at a stricture it is better to do a *suprapubic cystostomy* (and treat the stricture by dilatation later) than to make a local surgical attack on the lesion. External urethrotomy is seldom done *nowadays, recontraction* of the stricture being likely to follow. The Syme operation demands a passable stricture, which is better treated by other means. The Wheelhouse operation is preferable, but it is very difficult to trace the lumen through the actual stricture with or without the help of methylene-blue, and it is also difficult to find the urethra proximal to the stricture without retrograde instrumentation. The Loughnane operation is very useful; in it no attempt is made to trace the lumen through the stricture, which is simply bypassed by a catheter buried alongside it and lying in the urethra above and below. This false passage becomes epithelialised from each end and is subsequently treated by dilatation. Internal urethrotomy is not satisfactory —it seldom leads to lasting results and may even make the stricture worse—but it may be useful when a quick result is necessary, in true resilient stricture, and in patients who cannot attend regularly for dilatation. When it is possible to remove all the affected tissue (and particularly in single traumatic strictures of the perineal urethra) excision is probably the best treatment. It is necessary to do preliminary cystostomy and a free mobilisation of the urethra above and below the stricture, a procedure made safe by the vascularity of these tissues. If a gap has to be left it can usually be bridged by a catheter. Strictures of the prostatic and membranous urethra may be treated by a combination of excision and dilatation. In the perineal approach to these strictures great care must be taken not to damage the external sphincters.

Mr. **Terence Millin** described in detail the excision of strictures of the bulb. Before operation both ascending and descending urethrograms should be obtained and the plates superimposed so as to define exactly both limits of the stricture. As much as 6 cm. of stricture may be excised and there must be no tension on the suture line. No indwelling catheter should be left after operation. Patients treated thus may remain potent.

Dr. **Leander** (Stockholm) said that the worst strictures are those due to badly treated intrapelvic rupture of the urethra with fractured pelvis. He advocated a perineal operation, of which the three main principles are to excise all fibrosis, to mobilise the urethra thoroughly, and to leave no dead space under the skin.

Mr. **W. S. Mack** (Glasgow) presented figures showing that gonorrhœal stricture is becoming more common compared with ten years ago. Cases of "non-specific urethritis" may in reality be gonorrhœa treated with penicillin or a sulphonamide, and stricture may follow. Dilatation should be the standard treatment of stricture but operation is sometimes necessary and he is quite partial to internal urethrotomy. Excision (Marian's operation) is usually practicable only in traumatic stricture, since it is impossible to excise all the fibrosis left by inflammation. Stricture of the external meatus often involves the terminal urethra as well and cannot be treated by meatotomy. He creates an artificial hypospadias just proximal to the glans. Dilatation is useless.

Mr. **H. H. Stewart** (Bradford) described general contracture of the penile urethra and an operation he has devised for it similar to the Ombrédanne operation for hypospadias. This operation can only be done in patients with a foreskin. Potency is retained.

Mr. **H. P. Winsbury-White** (London) re-emphasised the importance and severity of strictures in the female.

Mr. **Wilfred Adams** (Bristol) recounted a case whose urethra became obliterated from the penoscrotal junction after prostatectomy (not by Mr. Adams).

Mr. **A. W. Badenoch** (London) considered the retropubic approach very difficult for strictures of the posterior urethra, though for the immediate treatment of the injury it may be suitable.

Mr. **E. T. C. Milligan** (London) referred to the work of Hamilton Russell and particularly mentioned his point that it is unnecessary to suture the whole circumference of the urethra in anastomosing after excision. The glands of Littré are mainly in the roof of the urethra, and most strictures are centred here, so internal urethrotomy rests on a sound foundation. He maintained that the indwelling catheter is an important cause of stricture.

Prof. **J. Hellstrom** (Stockholm) described an operation which can be used when it is impossible to find the proximal end of the urethra after excising a stricture. An artificial proximal urethra is constructed, and, when it is established, is anastomosed to the distal end. He uses a similar method for repairing the bile-duct.

Stones in the Kidney and Ureter

Professor **Hellstrom**, opening the discussion on June 25, when Mr. **A. Clifford Morson**, president of the association, was in the chair, compared his results in 1911–34 at Maria Hospital, and from 1940 onwards at Carolinen Hospital. In Sweden renal calculi are common and probably becoming more so. In 1911–14 there were 1244 cases of renal and ureteric calculi and in 1935–38 there were 16,312, and this increase could not be due only to improved diagnosis. Most cases did not require operation. A nutritional factor is probably mainly responsible for the increase in stone. Chemical analysis showed that 63% of stones were composed of oxalates or a mixture of oxalates and phosphates; 22% were classed as infective; 5% each were composed of uric acid and of phosphates; 5% were uncertain. Oxalate stones usually occur in young men, and there is often a history of gastro-intestinal upset. There is no evidence of an abnormally large dietary intake of oxalate. The stones probably originate in a focus of subepithelial calcification which grows, becomes extruded, and is finally detached. Stones due to infection are chiefly caused by urea-splitting organisms. Of 12 cases of hyperparathyroidism 6 had renal stones; the urinary excretion of calcium falls within 24 hours of the removal of the parathyroid tumour and the stones may then shrink.

In the treatment of ureteric calculi Professor Hellstrom is becoming more conservative. He does not agree with an American view that the stone should be removed by operation while it is still in the upper ureter simply to avoid the difficulties of the lower operation. About half of the ureteric stones are passed within a week of the first symptom, but some may remain in the ureter for as long as three years without harm. For stones held up in the lower ureter the midline approach has several advantages. It is important not to tilt the patient until the ureter has been secured above the stone, so as to prevent its slipping up to the kidney.

Reported recurrence-rates after operation for renal calculi range from 2 to 50%. For reliable figures long observation and close follow-up are essential. His own recurrences in 1911–34 totalled 25%, the 86 cases being divided into: fresh calculi on the operated side, 29; fresh calculi on the other side, 17; fresh calculi on both sides, 13; and calculi left behind at operation, 27. He now takes a radiogram of the kidney at operation, using a film in a pliable sterilised casette which can be put into the wound. Most "recurrent" stones result from either leaving behind at operation some minute concretions which later grow into stones, or infection. Blood-clot may be a focus of stone formation, so he advises irrigation before closing the pelvis and very careful hæmostasis. He does not usually drain the kidney. In the postoperative period sulphonamides, penicillin, and streptomycin may all be valuable, and early rising (on the first or second day) is an important preventive of thrombo-embolism. A further radiogram is taken before the patient leaves hospital and if a small stone is seen to remain it may be possible to wash it out with a ureteric catheter. His total mortality-rate is 5%, but since 1940 it has dropped to 1%. Recently the recurrence-rate has been lower than average (18%).

Mr. **Thompson Tait** (Melbourne) described cases of bilateral renal calculi and drew two conclusions—that every case of this sort must be dealt with on its merits, and that it is sometimes possible to benefit the most advanced case by suitable surgery. On the other hand there are cases in which operation is far better avoided.

Mr. **J. M. Ridley Thomas** (Norwich), in a paper on vesical calculus in Norfolk, noted that for centuries this county had an unusually high incidence of bladder stone. Surprisingly good results were sometimes obtained by the early lithotomists. At the beginning of the nineteenth century a surgeon performed 147 lithotomies with only 17 deaths. The records of the Norfolk and Norwich Hospital show that during 1910–30 the incidence of primary vesical calculus, particularly in children, sharply declined and it is now very rare. During these years the agricultural economy of the county changed from grain production to mixed farming and in the influence of this change on the diet of the people Mr. Thomas found the explanation of the disappearance of vesical calculus, the essential agent probably being vitamin A.

Mr. N. J. NICHOLSON (Louth) showed his X-ray apparatus for screening the kidney during calculus operations.

Mr. L. N. PYRAH (Leeds) said that the two factors for the production of calcification in the renal tubules are a high concentration of calcium in the urine and alkalosis. Alkalosis is the predominant factor when calcification occurs in pyloric stenosis and marasmus, whereas a high urinary calcium is the predominant factor in hyperparathyroidism, hypervitaminosis D, and multiple myelomatosis. The process can be studied by overfeeding rats with vitamin D. The calcium is deposited mainly in the tubules of the boundary zone. If the overdose is maintained for only 2–3 days the change is reversible and the calcium is eliminated in the next 12 days. A corresponding reversibility is seen in human hyperparathyroidism, of which Mr. Pyrah has studied 11 cases, 4 of them having renal calculi. In 3 of these cases the stones disappeared spontaneously after the removal of the adenoma. If pyloric stenosis is produced in the cat by tying a ligature round the pylorus, extensive cortical calcification is found when the cat dies after 5 days.

Dr. N. S. CONWAY (Glasgow) has investigated the urinary citrate excretion of patients with renal calculi. The normal urinary citrate excretion is 400–700 mg. a day and is unaffected by diet but is reduced by androgens and increased by a rise in the urinary pH. The average citrate excretion of patients with calculi is only 280 mg. a day; their blood-citrate and renal function are normal. But if these calculous patients are separated into two groups according to the presence or absence of infection in the urine it is found that the uninfected group have an almost normal citrate excretion (average 416 mg.) whereas those with infected calculi excrete on the average only 144 mg. of citrate a day. There is therefore no point in giving œstrogens to patients with sterile calculi.

Mr. WINSBURY-WHITE said that in 63% of cases of stone in the upper urinary tract there is evidence of infection in the genitalia, urethra, or bladder neck. Two important factors in reducing operative mortality for stone are the avoidance of instrumentation shortly before operation, and effective drainage.

Mr. N. O. T. GIBBON (Liverpool) described a case of nephrocalcinosis in a man of 32 who often passed mixed oxalate and phosphate stones and in whom the calcium excretion was three times normal. Giving citrates reduced the calcium excretion by 20%.

Mr. A. H. JACOBS (Glasgow) thought that the dissolution of calculi with buffered citrate solution has a definite place in the treatment of large branching calculi of the upper tract which are very difficult to remove completely by operation. After removing all he can he leaves a nephrostomy tube in the kidney and irrigates it with Suby's solution under repeated control.

Mr. E. W. RICHES (London) has used Suby's solution for treating calculi in paraplegics, but has had much better results in the bladder than in the kidney.

Mr. J. C. ANDERSON (Sheffield) described how a ureteric calculus disintegrated in six months after irrigation with "solution M," which contains twice as much carbonate as "solution G" and is less irritating.

Mr. T. L. CHAPMAN (Glasgow) showed that a small stone recurring after operation for a large stone may be much more serious than an untreated large one.

Mr. BADENOCH has not found "solution G" effective.

Mr. JOHN EVERIDGE (London) emphasised the danger of phosphate stones forming in patients under protracted treatment with alkalis for peptic ulcer and urged that X-ray films should be taken periodically to check this.

Short Papers

The third day was taken up with short papers and films. Dr. LOUIS MICHON (Paris) discussed the repair of exstrophy of the bladder; Mr. T. J. D. LANE (Dublin) described an uncommon blood condition simulating carcinoma; and Mr. HAMILTON BAILEY recalled some urological clinical entities frequently missed.

Reviews of Books

Anatomie Artistique

ARNOULD MOREAUX, membre de la Société des Artistes français. Paris: Maloine. 1947. Pp. 306. Fr. 850.

THE study of anatomy should be that of making "these dry bones live," though unfortunately to many medical students it becomes a static rather than a vital subject. The artist, however, does not depend on cadaver studies in his work, and while making his work active and living he sometimes loses by an imperfect knowledge of anatomy. This work, by an artist who is also an anatomist, has an original and instructive approach: it is a study of bones, joints, and muscles and is treated in such a way that the advanced student of anatomy can see the subject from a fresh angle. The pages are fewer than the illustrations, many of which comprise three or four individual studies. This follows Leonardo da Vinci's precept that an anatomical subject should be drawn from several different aspects which will give a much clearer idea of the subject than pages of written description.

The great value of the book as a whole is that it depicts movement—showing, for example, how and where movements of the vertebral column take place and the range of joint and muscle action. The positions of the arm and shoulder in different actions demonstrate muscular function in a manner seen in few anatomical textbooks, and other parts of the body are displayed in a similar way, bones and muscles being considered as active structures in groups or planes rather than as individual structures.

A return to graphic rather than verbal descriptive anatomy, as demonstrated by M. Moreaux, has much to commend it.

Primer of Cardiology

GEORGE E. BURCH, M.D., F.A.C.P., associate professor of medicine, Tulane University; PAUL REASER, M.D., instructor in medicine in the university. London: H. Kimpton. 1947. Pp. 272. 22*s*. 6*d*.

THE abundance of detail in this book may well confuse the beginner for whom it is intended. The description of gallop-rhythm, for example, is over-elaborate, and the authors might with advantage have borrowed from British work on this subject. In some cases the matter is inconsistent; thus the text states that arsenicals should never be used in syphilitic aortic incompetence, while a table above gives the doses of such drugs to be used in this condition. Again, auricular fibrillation and flutter are given among the pathognomonic signs of organic heart disease but are also said to occur in psychoneuroses. The presentation is designed to make the reader think for himself, and should do so, for every attempt is made—by discussion and illustration—to explain signs and symptoms on a physical and physiological basis.

The Legacy of Swift

Editor: MAURICE CRAIG. Dublin: Sign of the Three Candles, for the Governors of St. Patrick's Hospital 1948. Pp. 70. 5*s*.

IT is a remarkable paradox, but quite in keeping with the man, that Dean Swift, that professed hater of his fellowmen, should be the originator of one of the most beneficent institutions for suffering humanity ever established. But Swift under a grim and cynical crust possessed a deep and compelling sympathy, especially for the mentally afflicted. St. Patrick's Hospital, which he founded, and to which he bequeathed the whole of his fortune, has steadily gone on from strength to strength. It is now one of the foremost institutions of its kind, and, as is here pointed out by Dr. J. N. P. Moore, the present medical superintendent, and by Dr. J. D. H. Widdess, it is fully equipped with the most recent methods for the treatment of the mentally disabled. It is a far cry from the time when mental cases were exhibited, sometimes on payment of a fee, for the amusement or scorn of their barbarous contemporaries. The legacy of Swift has indeed come to fruition and this booklet tells the story of its development in a brief but arresting manner.

THE LANCET

LONDON: SATURDAY, JULY 3, 1948

Our Service

IN shelters, fo'c'sles, barrack-rooms, and other places of common resort, the talk often turned to the shortcomings of society. "But it will be different after the war," we used to say. And in the anxious winter of 1942 BEVERIDGE showed how it might be made different—how the nation could ensure that all its members, whether old or young, ill or unfortunate, should have a basic minimum of food and care. Being older and wiser, we now know that in times like these even social security is insecure; its money benefits would quickly be made worthless by inflation or external bankruptcy, and its stabilising influence in time of trial has to be weighed against its possible effect in discouraging effort when effort is so badly wanted. Moreover, in seeking Freedom from Want one may lose other freedoms, and Britain's recent advances towards Equality and Fraternity have been made at some cost to Liberty. The balance proper to our day and generation is hard to strike, and it may be long before we reach equilibrium. Yet with all these reservations it is certainly a source of strength to a country for its people to feel that, in peace as in war, the necessities of life will be shared according to need; and we can all be proud at least of the impulse behind the legislation that comes into force next Monday.

The new arrangements confer a great benefit on medicine by lessening the commercial element in its practice. Now that everyone is entitled to full medical care, the doctor can provide that care without thinking of his own profit or his patient's loss, and can allocate his efforts more according to medical priority. The money barrier has of course protected him against people who do not really require help, but it has also separated him from people who really do: and only time can show the relative proportions of the two classes. But though, as we hope, removal of this barrier will help to bring medicine to those who need it most, a truly satisfactory application of medical knowledge and resources demands much reorganisation and development both in general and hospital practice. Given time, the rationalisation of hospital services under State ownership should mean real progress in applied medicine, and anyone who has studied the membership of the boards and committees charged with their management must agree that our profession has been given a full opportunity for leadership If we continue to think of the National Health Service as a State service it will fail; but if we recognise it as our own service we can make it a great and increasing success For this we shall require all the sense of duty that training and tradition can inspire, and the result will ultimately depend on the standards of the teaching schools But our tradition is strong because it is a good tradition; and it will prevail

History at Geneva

CLINICIANS generally think of medicine as a personal art: "take care of the patients," they say, "and the populations will take care of themselves" For clinicians this may be right and proper and wise; but it is only penny wisdom if it blinds them to the benefits of the communal approach to health. Similarly a national outlook is pound-foolish if it discourages an international approach that would be for the general good; and only the most perversely insular will deny the immense potential significance of the World Health Assembly which opened in Geneva last week. The constitution of the World Health Organisation was signed two years ago by 61 nations—probably the greatest number that have ever agreed on any set of principles—and the new body is unique among United Nations special agencies in containing representatives of the Soviet republics. To everyone it appeals as a constructive effort; and it is a good basis for working together, because, as the Chinese delegate said, "no nation by gaining health takes it from another."

In our own country the public-health movement arose early last century from recognition that disease in the poorer sections of the community was a peril to all. In the same way the international movement is based first on the fact that "unequal development in different countries in the promotion of health and control of disease, especially communicable disease, is a common danger." Today, in a world growing rapidly smaller with the development of transport, there is increasing need of centralised epidemiological information and a central body able to take the kind of action required by last year's cholera epidemic in Egypt. As a defensive organisation W.H.O. assumes functions previously carried out by several others, including the Office International d'Hygiène Publique and the Health Organisation of the League of Nations, and it will also be continuing previous work when it provides us with international standards for drugs and biological products, an international pharmacopœia, and an international classification for diseases and causes of death But although there are obvious advantages in having all these necessary tasks undertaken by a single organisation, there is admittedly nothing very new or exciting about them What is really novel about W.H.O. is the size of its ultimate objective—"the attainment by all people of the highest possible levels of health" Nowadays not only do we know how to prevent the spread of infections, at relatively low cost, but also we know that scientific medicine, wherever it is applied, is capable of greatly increasing the health and strength, and therefore the prosperity, of mankind. The duty laid by its founders on W H.O. is to spread more widely the advantages now enjoyed by relatively few. The old negative conception is thus supplemented by a new positive one, and the World Health Assembly will have to decide exactly where, in this present year of grace, the emphasis should be placed.

Two widely different lines of policy might be followed Some of the participating countries—including some with long experience of international endeavour—believe that W H.O would do well to concentrate at first on the tasks which cannot possibly be undertaken by nations individually—epidemiological information, sanitary conventions, standardisation, and the like. The right course, as they see it, is to proceed quietly with this unspectacular work which may not interest the public but is unquestionably essential and is also inexpensive. At the other end of the scale are countries which see in W.H.O. a means of bringing the resources of science to vast populations now living in medical darkness. From the statement that W.H.O. makes no distinctions of race, political belief, or social condition they deduce that it should direct its gaze towards the East rather than the West, forming regional branches which could undertake big schemes for eradicating tropical diseases, training medical workers, and perhaps even subsidising hospital care. Between these extremes is the compromise policy placed before the assembly by the W.H.O. interim commission which has gone on with the work during the two years that have preceded ratification of the constitution.

Under the able chairmanship of Dr. Andrija Stampar, of Yugoslavia, who was last week unanimously elected president of the World Health Assembly, this commission has not only carried on defensive epidemiological services but has maintained technical missions in many countries and has initiated a very successful scheme of fellowships by which already 250 doctors and other health workers have gone abroad to gain experience or information. The fellowships and missions, which have hitherto been financed from the residual funds of Unrra, must undoubtedly be continued, and the missions ought to be extended to other than Unrra countries. In addition, however, the interim commission suggests that in the immediate future W.H.O. should tackle four major problems—malaria, tuberculosis, venereal disease, and the health of mothers and children. In so doing it would follow the example of the Rockefeller Foundation; rather than embark on large schemes of its own it would help countries to help themselves, and use its experts and its funds as catalysts. To fulfil this compromise programme the interim commission proposes a budget of some 6,500,000 dollars in 1949—a small enough sum when one considers the cost of national medical services or of other agencies of the United Nations. But even this modest demand now seems unlikely to be granted; for in the United States the World Health Organisation has unfortunately come under suspicion as a potential exponent of "socialised medicine," and in ratifying its constitution the Congress has made regrettable reservations, one of which is that the American contribution shall be limited to 1,920,000 dollars per annum while another is that the United States reserves the right to withdraw on a year's notice. If the United States contribution is scaled down, others are likely to be reduced in proportion.

Ratification with reservations is not exactly ratification; and though the U.S. delegation was last week provisionally admitted to full membership of the World Health Assembly its members find themselves in a slightly equivocal position. The U.S.A. has nevertheless set a valuable example by sending to Geneva an exceptionally large number of delegates, including representatives of unofficial bodies such as the American Medical Association. The assembly will have to decide whether in future years non-governmental medical agencies should be entitled to attend as observers—and if so which of them should be invited. Though this may seem a small matter, it is closely related to the question whether W.H.O. is going to remain a smallish official organisation with strictly limited functions, or is going to develop rapidly with the stimulating support from public opinion which it could easily enlist. In such a project, at such a time as this, it is very necessary to keep both feet on the financial ground; yet those responsible for the new venture must be well aware that money usually comes in the end to those who can prove that they would use it profitably. Nowhere more than in international effort is there need of faith, and Dr. Stampar was right in saying that if the World Health Organisation adopts a negative attitude, and does not treat health problems as of global importance, "it is bound to experience setbacks right from the beginning, and we shall gradually lose the faith in it which all of us express at present." In mutual aid between nations, as between individuals, lies our only real hope for the future, and the World Health Organisation has it in its power to play a notable part in the process of civilisation. In President Truman's words, we look to it "with hope and expectation."

Surgical Physiology of the Stomach

The flow of gastric juice is under dual control. There is a psychic flow, produced by the taste, sight, and even thought of food; and a chemical flow, provoked by the arrival of certain foods, particularly meat extracts, in the stomach. The psychic flow results from the passage of nerve impulses down the vagi, and can be imitated by stimulating the vagi electrically or abolished by cutting them. Edkins showed in 1906 that the chemical flow is due to gastrin, a hormone which is formed by pyloric mucosa in contact with appropriate foods and enters the blood-stream to reach the glands of the gastric fundus. The existence of gastrin, for long in doubt, has been confirmed by cross-circulation experiments and by the preparation of the hormone in a considerable degree of purity and free from histamine. It is a protein and is water-soluble. Experimentally it works only on intravenous injection and it stimulates the parietal cells only, the juice produced by its injection being poor in enzyme content. Gastrin is also responsible, as a humoral intermediary, for the psychic flow. Vagal stimulation induces a flow of gastric juice by causing the prepyloric antrum to elaborate gastrin. Thus excision or cocainisation of the prepyloric antrum almost abolishes the nervous flow from the fundus: whereas, if the antrum is isolated with its blood and nerve-supply intact, stimulation of the vagi produces an ample flow from the fundus. Cross-circulation experiments show that stimulation of the vagi of the donor animal will produce a flow of gastric juice in the recipient animal. Such experiments, repeated with a variety of modifications, have yielded the results, negative or positive, which the underlying theory would lead one to expect. Gastrin extracted from the human pylorus and duodenum, when injected into animals, will excite a flow of gastric juice which ceases thirty minutes after the injection. Though injection of purified gastrin will provoke only the parietal cells to activity, vagal stimulation yields gastric juice of full enzyme content. This suggests that the gastrin isolated is only a part of the pyloric antrum hormone and that, like secretin, it will be shown to consist of more than one chemical entity, each responsible for the secretion of an element of the gastric juice. A place for histamine in the control of gastric secretion is suggested by the findings that the fundus of the stomach contains more histamine than the pylorus: that gastric juice contains histamine which does not vary in quantity with the type of stimulus used: and that blood leaving the stomach does not yield histamine in increased quantity. Prof. G. S. KAHLSON, of Lund, who summarised the present knowledge of gastric secretion in a lecture at Guy's Hospital in May, postulates that gastrin liberates histamine locally in the gastric fundus and that histamine is thus the immediate stimulus to the gastric cells, but he would not yet raise this hypothesis to the status of a theory.

It is notoriously dangerous to apply experimental results from animals to the treatment of human beings, because human and animal physiology show subtle but important differences. The limited experimental work on man, however, suggests that man and the laboratory animal control their gastric secretion in the same way and justifies physiological reflections on the surgery of peptic ulcer in man. The aim of surgery is to reduce the flow of gastric juice which is the immediate cause of peptic ulceration: and in theory it should be possible, where medical treatment has failed to relieve symptoms, surgically to weaken or break the physiological chain of gastric secretion in three different places. The vagi might be cut to abolish the psychic flow; the pyloric antrum and duodenum might be removed to ablate the tissues forming gastrin; or the stomach from cardia to pyloric antrum might be resected to put the peptic juice factory out of business. In practice most operations for peptic ulcer make an incomplete attack at more than one point. A vagus resection is incomplete because it tackles only the psychic flow, and some advocates of this operation believe that pyloric antrectomy—for gastric ulcer at any rate—should accompany the vagus resection. Partial gastrectomy attacks the formation of both gastrin and peptic juice, but it does neither completely. How miserably it fails to prevent fresh ulceration if the pylorus must (for technical reasons) be left behind is known to all gastrectomists. The finding that gastrin is also formed in the duodenum might mean that the removal of more duodenum would improve the results of gastrectomy. Many surgeons, but by no means all, believe that very high gastrectomies are the operations of choice: and it is certain that the higher the gastrectomy the greater the destruction of tissues forming gastric juice Nevertheless only total gastrectomy destroys all the cells forming gastric juice and this is the only procedure which will guarantee a patient against recurrent ulceration, though at the cost of a variety of undesirable side-effects, not to mention an increased risk of dying from the cure.

The moral seems to be that an incomplete interruption of the physiological chain of gastric secretion at more than one point gives the best results at present obtainable in the surgery of peptic ulcer. But the surgeon might consider whether removal of more duodenum at gastrectomy would yield better results; and whether redoubled precautions to guard against reflux of food into the duodenal stump would lessen gastrin formation by depriving the duodenum of its physiological stimulus.

B.P. 1948

THE *British Pharmacopœia, 1948*,[1] which will come into force on Sept. 1 and is not yet on sale, is a handsome volume, clothed in scarlet and embellished with gold lettering—a brave attempt to gild a pill of enormous dimensions made up of an astonishingly heterogeneous collection of ingredients. There are about 600 pages of monographs describing drugs and preparations; the 24 appendices, mainly concerned with physical and pharmaceutical chemistry, fill another 200 pages: and it is significant of the scope of the work that the index contains well over 4000 items.

Lists of deletions and additions should not be taken at face value, for here and there a drug is deleted merely because of a minor change of name. Thus ergometrine is apparently "struck off strength," but is immediately reinstated as ergometrine maleate. Similarly about a score of these items are "new" only in a strictly official sense, for such old friends as calamine lotion and emulsion of paraffin oil are like good wine that needs no bush. Again, sodium metabisulphite, an ingredient of half a dozen official injections, is a preservative of interest only to the manufacturing chemist: and terpineol is introduced merely as a perfume for the solution of chloroxylenol. Nevertheless, the status of such compounds is a matter of some moment to the pharmacist. Then in future we must try to say ipomœa when we think of scammony (which happily is not often), and ouabain rather than strophanthin. The soluble forms of drugs such as barbitone, phenobarbitone, fluorescein, and saccharin are now more precisely described as sodium compounds—e.g., sodium barbitone for soluble barbitone. Similarly phemitone is called methylphenobarbitone; and instead of the word pulverata to indicate a powder suitably standardised, as in digitalis pulverata, we read preparata.

Besides the additions made in the seven addenda of the past twelve years, the new volume contains 155 new names. The most impressive series of newcomers is the 57 injections, which bring the total up to 84, compared with a mere half-dozen in the *B.P. 1932*. Here again, however, the majority are familiar remedies now made immediately available in this convenient form. These include such commonplace substances as morphine sulphate, adrenaline tartrate, atropine sulphate, dextrose, neo-arsphenamine, sulpharsphenamine, ouabain, strychnine hydrochloride, sodium phenobarbitone, Ringer's solution, and many others. The modern tendency to produce pure chemical substances for therapeutic use continues to be reflected in the introduction of a large number of new remedies which can be injected if necessary—e.g., digoxin, ergometrine maleate, mepacrine methanosulphate, neostigmine methyl sulphate, pethidine hydrochloride, and suramin. Hormonal preparations are often most suitably dispensed in this form.

---

[1] To be published for the General Medical Council by Constable & Co. Ltd., London. Pp. xl — 914.

and there are now official injections of desoxycortone acetate, chorionic (and serum) gonadotrophin, ethisterone, hexœstrol, œstradiol dipropionate, œstradiol monobenzoate, progesterone, and testosterone propionate. Separate injections are now official for vasopressin and oxytocin. Vitamin K as menaphtone and vitamin B_1 as aneurine hydrochloride are, as expected, now available as injections. Notable miscellaneous injections include those of diodone and of iodoxyl which are intended for pyelography. Soluble salts of sulphathiazole and of sulphadiazine are official preparations for parenteral administration. Ethanolamine oleate is used as a sclerosing agent for varicose veins. Vinyl ether has earned approval presumably because experience has shown that in expert hands it is a valuable general anæsthetic. A growing literature shows how difficult it is to combine efficiency with safety in cocaine substitutes. Butyl aminobenzoate and butacaine sulphate (known by the trade names 'Butesin' and 'Butyn') and cinchocaine hydrochloride join amethocaine and orthocaine. Among drugs used as basal anæsthetics are the sodium salts of hexobarbitone and thiopentone, which have long been in common use as 'Evipan' and 'Pentothal.' Picrotoxin, which is firmly established as the drug of choice in barbiturate poisoning, is now official; and phenytoin represents the newer drugs for the treatment of epilepsy. Thiouracil and methylthiouracil are included, and so are papaverine and pethidine, which share an antispasmodic action but differ in other important respects. The original flavine antiseptics did not fulfil expectations, some tending to delay the healing of wounds, but the best of these compounds, proflavine, becomes official as the hemisulphate. Suppositories of old familiar drugs (cocaine, hamamelis, &c.) have returned to the pharmacopœia. The list of vaccines is growing, but the only recent ones that interest the practitioner in Britain are those for the treatment or prevention of acne, whooping-cough, staphylococcal infections, and tuberculosis. The use of tubercle bacilli as an antigen brings the *B.P.* into line with its continental equivalents.

Much wholesome pleasure can be derived from deleting the names of drugs from a pharmacopœia. Thus there will be general satisfaction on finding that upwards of 100 articles and preparations included in previous editions find no place in the *B.P. 1948*; but this is not to say that the Commissioners' reasons for lightening the load will always be appreciated. For example, ammonium carbonate is banished, but ammonium bicarbonate (possessing all the virtues of the carbonate, such as they are) takes its place. Several aromatic waters are excluded, but one (aq. menth. pip.) is replaced by a concentrated water. Few will lament the passing of hoary remedies whose title-deeds to therapeutic potency are lost in antiquity; such are copaiba, buchu, asafœtida, and sandalwood oil—drugs which were once esteemed as urinary antiseptics. Not a few drugs formerly official have been discarded because more active preparations are now preferred; dry extract of liver, powder of vitamin B_1, anti-dysenteric and anti-pneumococcal serum, Easton's syrup, injection of iron, carbromal, and injections of mercury and calomel are all examples of this type. To exclude hexamine on the same grounds seems odd, for even if the sulphonamides have ousted hexamine it is undoubtedly a potent drug in large doses. Other preparations can be sacrificed more readily because they have objectionable side-effects; such are methylsulphonal (though sulphonal remains), cantharadin (including liquor epispasticus), jalap, chrysarobin ointment, and sulphapyridine. Eight infusions and the majority of 17 tinctures are deleted for reasons best known to the pharmacist or on grounds of redundancy.

Many doctors will be surprised and perturbed to find some of their most cherished remedies thrown on the scrap heap. The confections of senna and of sulphur, lobelia, linseed, black wash, and the solution of glyceryl trinitrate no longer claim monographs; but it is comforting to know that many drugs which do not pass muster for the *B.P.* are listed in the *B.P.C.*; and who shall say that none of these will regain its former status in some future edition?

Annotations

REMUNERATION

Laymen reading successive reports from the Spens committees have been known to question the need to improve the financial position of doctors and dentists in relation to other people. They remark that such improvement was not part of the original programme for a public medical service. Doctors, on the other hand, can fairly reply that it was no part of the original programme to lower the standard of living of professional men and women who are doing good and necessary work. The Minister's message on p. 24 suggests that he accepts this principle, and we hope he will be able to give early attention in particular to the situation of the country doctor with a relatively small potential number of patients—a situation which has been well presented in our correspondence columns and was discussed by the representative body of the British Medical Association last week. As was pointed out at the representative meeting, one of the difficulties of payment by capitation fee is that any doctor trying to give really good attention to a small number of patients—and perhaps prevented geographically from augmenting that number—is at a serious monetary disadvantage, and a speaker suggested that the deserving general practitioner in such circumstances should be entitled to some additional emolument for merit, on the lines of the "distinction awards" which the Spens Committee has proposed for specialists.

This suggestion is the more interesting coming at a time when the Spens proposal is itself under fire. Its opponents say that all sorts of personal difficulties will arise if any primarily professional body has to decide on unequal payment of doctors holding similar appointments. Certainly the awkwardness of choice will be increased by the fact that the three awards of £500, £1500, and £2500 differ so widely, and the committee's task might be less formidable if these awards took the form of promotion to one of three ascending scales in which length of service would again operate. Complaints might also be reduced if the regular increments granted to all specialists did not cease quite so abruptly and so early in their career. Such minor modifications, however, do nothing to meet the main objection that a small central committee cannot possibly know much about all the candidates, and that the chances of personal acquaintance might therefore affect its decisions. In answer to this, the suggestion has been put forward that the awards should be made in the regions, by regional appointments committees which would know more about the people concerned. On the other hand, it would be manifestly unfair to allot each region a quota calculated on any rigid scale, and there appear to be strong arguments for leaving the ultimate decision to a central body. We share the opinion of Dr. Cochrane Shanks,[1] who was a member of the Spens Committee, that the principle of making the higher salaries conditional on special merit and ability is a proper and necessary means of encouraging initiative, and we are glad to note that he pictures the national committee making its final selections "only after considering most carefully the recommendations from regional boards, teaching hospitals, Royal Colleges and Corporations, and specialist associations."

Other related questions which burn brightly are the remuneration of doctors directly employed by the Government and local authorities and the remuneration of teachers. The Minister has already shown himself aware of the anomalies that arise from payment of teachers in medical schools at rates far below those obtainable in the public service by men and women of equal or inferior qualifications,[2] and we are glad to hear that the council of the British Medical Association is seeking immediate negotiation to secure that the recommendations of the Spens Committee on the remuneration of specialists are made applicable to full-time teachers and laboratory workers.

ADRENALINE AND INFECTIONS

When a bacterial suspension is inoculated into guineapig skin and muscle, the resulting infection is much more severe if a small quantity of adrenaline is injected at the same time. Evans and colleagues[3] show that the degree of enhancement varies with the species of bacterium used from twice to a hundred-thousand-fold and is most pronounced with *Cl. welchii* and *Cl. septicum*. In their experiments the effect of bacterial toxins was increased only slightly by the addition of adrenaline, and there is reason to think that the enhancement of infections was due to the inhibition of diapedesis of leucocytes and to interference with the mobilisation of the other primary defences of the body; possibly the local ischæmia also prevents the early removal of bacteria from the site of infection. The dose of adrenaline used was insufficient to damage the tissues permanently, and the effect must not be confused with that of such substances as calcium chloride which produce sterile necrosis in the absence of bacterial infection.

Have these findings any application to clinical practice? Cooper[4] reported a case of gas-gangrene in man following the injection of adrenaline and showed experimentally that 62·5 μg. of adrenaline reduced the minimum lethal dose of *Cl. welchii* for a guineapig to 1/10,000 of the dose without adrenaline. The dose used by Evans and colleagues was only 2 μg. Even allowing for differences in body-weight (which are probably of small importance for a drug having a strictly local action) doses many times as great as these are used daily in local anæsthesia, and experience has shown that, given the usual aseptic precautions, local infections after the use of adrenaline are extremely rare. Many surgeons avoid local anæsthesia in the presence of gross sepsis, and with good reason: but it must be remembered that the early local anæsthetics themselves had some slight cytotoxic action. With the improvement of these drugs it might be worth while to investigate the validity of this old tabu.

There are several established practices based on laboratory work whose application to clinical medicine is on unsure ground. For example, is the doctor justified in withholding anti-typhoid inoculation during an epidemic for fear of rendering the patient more susceptible to infection during the negative phase? The answer is that we just do not know, but the objection is raised in every outbreak of enteric infection. Similarly the paper under discussion may lead to the omission of adrenaline from local anæsthetics with which it has been incorporated for very good reasons. The careful experiments of Evans and colleagues do not pretend to reproduce the conditions of clinical practice and they do not seem to call for any change in current procedure. They do suggest however that someone might profitably make a detailed clinical and bacteriological examination of the effects of local anæsthesia in the light of modern knowledge.

IN SEARCH OF BETTER HOSPITALS

Impressed by the need for a re-examination of the purpose and pattern of our hospitals, the Nuffield Provincial Hospitals Trust has joined with the University of Bristol in sponsoring a detailed investigation. The time, as we have suggested,[1] is apt: for years must elapse before new construction makes good existing deficiencies and meets the fresh needs of the new service. The Nuffield research programme concentrates principally on aspects which may be clarified in the 2–3 years that the inquiry will continue. It will be undertaken by a whole-time team, including representatives of a number of interested professions, under the direction of Mr. John Madge, A.R.I.B.A., with Mr. L. Farrer-Brown, secretary of the trust, as coördinating chairman. The investigators are setting themselves to gain a panoramic picture of the hospitals' structure and life, and at points their study will run parallel with the hospital job-analysis which is already proceeding under the ægis of the trust. But beyond that an attempt will be made to look at planning "with fresh unprejudiced eyes," and to review the distribution of work between hospitals and other health agencies—a scrutiny that is long overdue. Not the least of the advantages that may accrue from this programme is the stimulation of long-term research in the same field.

DAMAGE AT ENDOSCOPY

Injury to the pharynx and œsophagus, whether by swallowed foreign bodies, endoscopy, or flying missiles, has always carried a grave risk of death from suppurative mediastinitis and toxæmia. Thoracic suction and the loose bed of cellular tissue in which the mobile pharynx and œsophagus lie give rise to a rapidly developing surgical emphysema and spreading infection which ordinary surgical drainage has little power to arrest. In consequence of this, an ultra-conservative attitude has been adopted in cases of accidental perforations occurring during œsophagoscopy or gastroscopy, treatment being limited to chemotherapy and prohibition of fluids by mouth. Some endoscopists have advised incision of the neck to open up the fascial coverings in the region of the tear and packing of the wound to prevent surgical emphysema and spreading cellulitis, and this is a method which has given excellent results in penetrating wounds of this region in the recent war.[2] Before the days of penicillin, cellulitis and sloughing of the tear in the pharynx or œsophagus either prevented adequate suturing or ruined it through postoperative infection, but, now that penicillin can prevent this, prompt surgery can undoubtedly save patients who have sustained a tear of the œsophagus through endoscopy. Fletcher and Avery Jones[3] pointed out that the common site for tears after œsophagoscopy and gastroscopy is

Thiouracil and methylthiouracil are included, and so are papaverine and pethidine, which share an antispasmodic action but differ in other important respects. The original flavine antiseptics did not fulfil expectations, some tending to delay the healing of wounds, but the best of these compounds, proflavine, becomes official as the hemisulphate. Suppositories of old familiar drugs (cocaine, hamamelis, &c.) have returned to the pharmacopœia. The list of vaccines is growing, but the only recent ones that interest the practitioner in Britain are those for the treatment or prevention of acne, whooping-cough, staphylococcal infections, and tuberculosis. The use of tubercle bacilli as an antigen brings the *B.P.* into line with its continental equivalents

Much wholesome pleasure can be derived from deleting the names of drugs from a pharmacopœia. Thus there will be general satisfaction on finding that upwards of 100 articles and preparations included in previous editions find no place in the *B.P. 1948*; but this is not to say that the Commissioners' reasons for lightening the load will always be appreciated. For example, ammonium carbonate is banished, but ammonium bicarbonate (possessing all the virtues of the carbonate, such as they are) takes its place. Several aromatic waters are excluded, but one (aq. menth. pip.) is replaced by a concentrated water. Few will lament the passing of hoary remedies whose title-deeds to therapeutic potency are lost in antiquity; such are copaiba, buchu, asafœtida, and sandalwood oil—drugs which were once esteemed as urinary antiseptics. Not a few drugs formerly official have been discarded because more active preparations are now preferred; dry extract of liver, powder of vitamin B_1, anti-dysenteric and anti-pneumococcal serum, *Easton's* syrup, injection of iron, carbromal, and injections of mercury and calomel are all examples of this type. To exclude hexamine on the same grounds seems odd, for even if the sulphonamides have ousted hexamine it is undoubtedly a potent drug in large doses. Other preparations can be sacrificed more readily because they have objectionable side-effects; such are methylsulphonal (though sulphonal remains), cantharadin (including liquor epispasticus), jalap, chrysarobin ointment, and sulphapyridine. Eight infusions and the majority of 17 tinctures are deleted for reasons best known to the pharmacist or on grounds of redundancy.

Many doctors will be surprised and perturbed to find some of their most cherished remedies thrown on the scrap heap. The confections of senna and of sulphur, lobelia, linseed, black wash, and the solution of glyceryl trinitrate no longer claim monographs; but it is comforting to know that many drugs which do not pass muster for the *B.P.* are listed in the *B.P.C.*; and who shall say that none of these will regain its former status in some future edition?

Annotations

REMUNERATION

LAYMEN reading successive reports from the Spens committees have been known to question the need to improve the financial position of doctors and dentists in relation to other people. They remark that such improvement was not part of the original programme for a public medical service. Doctors, on the other hand, can fairly reply that it was no part of the original programme to lower the standard of living of professional men and women who are doing good and necessary work. The Minister's message on p. 24 suggests that he accepts this principle, and we hope he will be able to give early attention in particular to the situation of the country doctor with a relatively small potential number of patients—a situation which has been well presented in our correspondence columns and was discussed by the representative body of the British Medical Association last week. As was pointed out at the representative meeting, one of the difficulties of payment by capitation fee is that any doctor trying to give really good attention to a small number of patients—and perhaps prevented geographically from augmenting that number—is at a serious monetary disadvantage, and a speaker suggested that the deserving general practitioner in such circumstances should be entitled to some additional emolument for merit, on the lines of the "distinction awards" which the Spens Committee has proposed for specialists.

This suggestion is the more interesting coming at a time when the Spens proposal is itself under fire. Its opponents say that all sorts of personal difficulties will arise if any primarily professional body has to decide on unequal payment of doctors holding similar appointments. Certainly the awkwardness of choice will be increased by the fact that the three awards of £500, £1500, and £2500 differ so widely, and the committee's task might be less formidable if these awards took the form of promotion to one of three ascending scales in which length of service would again operate. Complaints might also be reduced if the regular increments granted to all specialists did not cease quite so abruptly and so early in their career. Such minor modifications, however, do nothing to meet the main objection that a small central committee cannot possibly know much about all the candidates, and that the chances of personal acquaintance might therefore affect its decisions. In answer to this, the suggestion has been put forward that the awards should be made in the regions, by regional appointments to an increase of ½d. on the average dispensing fee, with little dissent. The average dispensing fee has been fixed at 1s., and at the end of three months, when the relative frequency of prescribing mixtures, tablets, ointments, &c., has been determined, the appropriate fee for each class of medicament will be fixed; fees will vary with quantity and dosage. Sterile preparations, eye drops, bougies, suppositories, lozenges, cachets, blisters, and other less common methods of administration will carry special fees. The Government expects about 140 million prescriptions to be dispensed each year. The average fee for all prescriptions under N.H.I. terms is only 6·2*d.* and though the new fee is almost double this figure, many chemists believe that the dispensing department will continue to be subsidised from sales at the counter. In addition chemists will receive a $33^1/_3\%$ profit on the buying price of ingredients, a substantial addition on the higher-priced proprietary preparations but a trifling sum on practically all formulary preparations. For each prescription, irrespective of the medicament required, a container allowance of 2½*d.* will be paid and the chemist must supply a suitable container without charge to the patient. For rota duties after the normal closing hour, which will probably be 6 P.M., a service fee of 7*s.* an hour will be paid, and for service on Sundays and Bank Holidays this will be increased to 12*s.* 6*d.* an hour. For the next three months, until the final allocation of fees is determined, the dispensing fees in the Drug Tariff will be increased by 161·5%, bringing the average fee up to about 1*s.* In Scotland, where the loss of private dispensing will be of serious consequence to chemists, an average fee of 1*s.* 3*d.* has been rejected, though discussions continue. An impartial inquiry on the lines of the Spens Committee has been demanded on behalf of the pharmacists, and they have agreed to accept its findings.

THE ACCELERATED ELECTRON

THE electron has now to conform to man's requirements; gone are the days when it was merely observed as an object of curiosity—it has become a very valuable tool. We know nothing of the electron at rest; only in motion does it betray its presence, and it happens to be the easiest particle in the world to accelerate. The first application of the accelerated electron was in the gas-discharge tube, studies of which led to the discovery of X rays two years before electrons were themselves discovered, so we were using them many years before we knew they existed. Since then "acceleration" has been the keynote of action, and the two ways of changing the state of motion of the electron have been exploited to the full. Since moving electrons behave like an electric current they can be accelerated or retarded by a magnetic field, whereas by virtue of their charge alone they react similarly if brought into an electric field. The electric field was at first the chief agent for producing high-speed electrons, and the method was to apply a steady electric field of the maximum voltage needed to realise a certain speed; the more ingenious modern methods accelerate the electrons in jumps magnetically, the interval between jumps being about a hundredth of a second. This magnetic pushing is the principle of the synchrotron, which gives the electrons a speed equal to that produced by 30 million volts; yet, because the magnetic impulses are synchronised with the arrival of the electrons at one particular region of the circuit, the operating voltage has nowhere to be greater than in an ordinary wireless circuit.

High-speed electrons can be used as such or can be made to hit a target, so producing very penetrating X rays. Technically the radiotherapist wants the most penetrating radiation possible, for with this he can more easily attain the desired depth and surface intensities with minimal damage to the skin and normal structures. But there is one unresolved consideration which may make him hesitate before using 300 *million volt rays*, for it is an experimental finding that such penetrating rays can render the tissues they traverse radioactive; it is a feeble radioactivity but it may well act as a danger sign. The acceleration of electrons is now being applied to fluoroscopy. If the electrons are accelerated just before they reach the fluorescent screen, their increased energy will excite the crystal matrix to greater luminosity. This is done by allowing the X rays that have passed through the body to fall on a screen which readily emits electrons, and then to introduce an electric field between this electron surface and the fluorescent screen. The originator of this idea is Edward Chamberlain, of Philadelphia, and it has been successfully worked out by J. R. Coltman, physicist to the Westinghouse research laboratory. Any device which reduces the exposure of the radiologist to X rays will be sure of a welcome.

D'ARCY WENTWORTH THOMPSON

Sir D'Arcy Thompson, who died on June 21, was appointed professor of biology in University College, Dundee, in 1884, at the age of 24; and in 1948, at the age of 88, he still graced the chair of natural history in St. Andrews University. During those long years of teaching he had befriended and inspired succeeding and growing classes of young men and women at the most impressionable stage of their training. His earliest class—for there was only one student—recalls that skeleton-mounting and preparation of specimens filled most of the course, but for one hour each day the class assembled and was entranced by a formal lecture, beginning: "Sir,——." The following passage, taken from Thompson's review of some of Ronald Ross's poetry, will serve to illustrate the power over words and thoughts that afterwards delighted so many generations of students:

> "Only a few days ago, lecturing to my class of some eighty young men and women newly entered a week before upon their medical course, I tried to tell them what Protozoa meant to our fathers, and what (thanks to Pasteur and Grassi and Patrick Manson and David Bruce and Ronald Ross and many another) they have come to mean to us. In my student-days an Amœba, a bell or slipper animalcule, a little ooze from the Atlantic, a few radiolarian or foraminiferal shells, told us all we knew of Protozoa. Today a new world is opened, in which we hear of tiny things with strange life histories, of momentous chains of cause and consequence wherein rat and louse and gadfly and mosquito play their insidious part, bringing fever to the swamp and murrain to the plain: we are told at last of mysterious maladies explained; of epidemics held at bay, of territories and peoples emancipated from disease. And then as an example of the spirit of the scientific physician, of aims conceived, of dreams come true, I ventured to read them a couple of Ronald Ross's early verses. . . . My students listened and went quietly away, and I could see by their faces that they had heard the words of the poet and physician, as though he were speaking to them."

A poet and scientist was indeed speaking, and many heard him.

AN OCTOGENARIAN *PRACTITIONER*

WITH its July issue the *Practitioner*, founded in 1868 by Dr. F. E. Anstie, of the Westminster Hospital, celebrates its eightieth birthday. Its first volume is reviewed by Dr. W. R. Bett, who also gives a brief account of its contemporaries. An article contrasting 1868 and 1948 as regards world affairs, social conditions, and medicine is contributed by Sir Heneage Ogilvie, the present editor.

BY June 26 16,537 doctors in England and Wales and 1976 in Scotland had joined the National Health Service. By the same date 7,400,000 patients not previously covered by health insurance had been enrolled.

the posterior wall of the lower pharynx and upper œsophagus, and Hermon Taylor[4] indicated how this resulted from pressure between the instrument and the prominent convexity of the extended cervical spine, rather than from any anatomical weakness of pharyngeal wall. In his article last week (p. 985) Mr. J. C. Goligher takes the view that the œsophagopharyngeal wall should always be explored in patients developing surgical emphysema in the neck after endoscopy, provided the endoscopist can exclude damage, for example by biopsy or dilatation, to the lesion for which the examination was undertaken. Most gastroscopists and œsophagoscopists would perhaps advocate a more cautious approach, since clinicians with experience in this field will recall many cases with excessive soreness in the throat and perhaps a degree of swelling in the neck which they have felt must have been due to a small laceration, and which have readily recovered with chemotherapy and the withholding of fluids. However, if such a case shows no sign of limitation, Goligher's plan of prompt operation is the correct one, with the object of suturing the tear as he describes; and if this is impossible, the wound should be packed and drained.

DISTRIBUTION AND SAFETY OF MILK

THE Williams Committee on milk-distribution, which reported last month, recommended the setting up of an independent commission to take over the responsibility of the Ministry of Food for the marketing of milk. It suggested that the commission should operate experimentally as processor and retailer, with monopoly powers, in one or more of the new satellite towns. Such a commission would take over some of the functions of the Milk Marketing Board, which has done much to stabilise prices for the farmer since the depression of the 1930's. It is therefore not surprising that there should be strong opposition from farmers to these proposals.[5] The committee believes that its scheme would be preferable to the alternative of public ownership both now and in the more distant future, but two of its members consider that public ownership and operation would ultimately secure greater economies.

The committee urged the application of compulsory heat-treatment to all milk except in remote areas. For the present it would exempt T.T. milk, "which largely protects the consumer from at least the most serious of the milk-borne diseases," but it would prohibit from the outset the retail sale of accredited milk in any area scheduled for heat-treatment. The Government have now decided to introduce a Bill to prevent milk from being sold retail unless it has been heat-treated or is sold as T.T. milk or accredited milk from a single herd. There is no scientific justification for the exclusion of accredited milk from heat-treatment, even if it comes from one herd. Accredited milk is usually cleaner than non-accredited, but it has no greater freedom from disease. On the average, milk from any one herd will contain tubercle bacilli less often than bulked milk, but when it does the infection will usually be much more severe. The Government's reason for not accepting this recommendation of the Williams Committee appears to be the practical one that facilities for heat-treatment are insufficient. The Milk Marketing Board will be establishing an experimental creamery in Durham which will offer producer-retailers facilities for heat-treatment which they could not afford for themselves individually. If the scheme is successful these facilities will presumably be extended to other areas as rapidly as possible.

It is of the utmost importance to dairy farmers and milk consumers that better progress should be made with the attested herds scheme, so that within the next few years groups of parishes and then whole counties can be cleared of bovine tuberculosis. A recent summary[6] of the progress already made shows that there are now over a million cattle in attested herds. As was emphasised during the Parliamentary debates on the Veterinary Surgeons' Bill, the control of tuberculosis and other diseases of cattle contributes directly to public health and also increases the efficiency of milk production.

PHARMACY IN THE SERVICE

ALL dispensing in the National Health Service, except the relatively small volume done by doctors in rural areas, will be in the hands of retail pharmacists and is likely to remain there at least until health centres are firmly and widely established. No extensive examination of the position of pharmacy has been attempted since the inquiry instigated by the Pharmaceutical Society over a decade ago, but a concise picture of present-day conditions emerges from the report[7] of a working party set up by the Minister of Health and the Secretary of State for Scotland to study the dispensing practices in their respective domains. The working party estimates that in England and Wales 80% of practitioners now undertake dispensing for their private patients, whereas in Scotland the figure is only 10%. Hence the English pharmacist must expect a large increase in his "non-insurance" dispensing and this will usually involve enlarging the dispensary. Shortage of staff may prove an additional difficulty, but most qualified dispensers are not fully employed on this work; the average usual output per dispenser was found to be 6390 prescriptions in England, 4040 in Wales, and 5120 in Scotland, whereas an expert dispenser, working in a properly equipped dispensary, might be expected to deal with 9000 prescriptions a year, or about 4 per working hour. This potential output could be increased in areas where prescribing follows a common form but in a London West End pharmacy, following the best traditions of the craft, 3 prescriptions an hour is perhaps the maximum capacity of the pharmacist. Man-power shortage can be reduced by the use of non-dispensers for many ancillary tasks in the pharmacy.

Prescribing habits differ widely in the two countries; in England over 83% of mixtures in insurance practice are prescribed from formularies, either the National or the *B.P.C.*, and 37·8% in private practice, against only 3·5% and 1·3% respectively in Scotland. In Scotland, however, about 19% of mixtures are prepared from doctors own formulæ, a feature which is absent from English and Welsh prescribing; ointments prescribed show a similar trend. The shelves of English pharmacies contain an average of 12 stock mixtures, all of which are prepared on the premises and used within a few days; these time-saving devices are not used in Scotland or in Wales. Concentrated stock mixtures are little used throughout Great Britain. Scottish pharmacists look on each prescription as a thing apart, ordered for the needs of a particular patient, and maintain that it should be compounded from scratch; the English pharmacist contends that the small errors which are inseparable from all processes of measurement are reduced to a minimum in the larger quantities involved in stock preparations.

The terms offered to English and Welsh pharmacists for participation in the new service have been accepted with only a token resistance movement in a few areas. A conference of pharmaceutical committees and branches of the National Pharmaceutical Union, which represents proprietor chemists, first rejected the terms offered, but then accepted an amended offer, regarded as equal addition give an atmosphere of individuality to each hospital; others require personal service, and it would be an unhappy day when that were cast out from our midst. A house committee will not manage its hospital, but it will have a valuable function in advising the management committee and in meeting these indefinable needs of the hospital patient.

[7] Report of the Working Party on Differences in Dispensing Practice between England and Wales and Scotland. H.M. Stationery Office. 1948. Pp. 40. 1s.

As chairman of a hospital management committee the first thing I can see is that groups of hospitals which used to go their own way will now be united under a single managing body. This offers an immediate opportunity for the staff, both senior and junior, to get together and inquire what service they can render, not to one unit alone but to the group. It also creates for the first time a real chance for the visiting consultant to become an active member of the staff of the hospital in which he used to pause for an hour or two on his great journey.

THE EXECUTIVE COUNCIL

First to be established among the many new bodies needed to administer the National Health Service Act, the executive councils suffered at the start because of this priority. They were set up when medical opinion was running strongly against the Act, when every move of the Minister was regarded with suspicion, and when any coöperation offered was likely to be grudging and conditional. Moreover, they had to try to weld into an executive whole elements drawn from five distinct (and potentially antagonistic) sources. Three of the groups were professional, severally representing the doctors, the dentists, and the pharmacists, while the rest were governmental—nominees of the local health authority and of the Minister. The Minister's nominees were mostly survivors of the old insurance committees, often having strong associations with approved societies. It can hardly be said that this pattern gave promise of easy coöperation. Nevertheless in most areas things have worked out better than might have been expected. The local medical committees chose doctors of experience to represent them, and the expert professional advice they have been able to afford on a host of different complicated schemes coming before the council for ratification has done much to promote respect and understanding for the doctor's point of view.

The executive councils have found it necessary to set up financial and other subcommittees. Doctors have been afforded a full share of responsibility in these subcommittees, and have often been chosen as chairmen or deputy chairmen. Particularly in the larger local-authority areas, the need for liaison with such bodies as the hospital management committees—of which there may be twenty or more within the boundaries of the larger counties—has thrown a considerable extra strain upon the already overtaxed time of council members. The doctors have had to accept part of this responsibility, each taking his place on the appropriate local hospital committee.

The executive machine must at present run in top gear, if it is to be able to cope with the influx of applications and settle the problems of patients and doctors proposing to participate in the service. Soon this initial work should quieten, and more time and thought can then be spared to face the tasks the future holds. Predominant among these must be the establishment of health centres. By the time this appears on the agenda the doctors in most counties will probably have settled into a relationship with their colleagues on the council that will give them considerable authority in discussion.

The doctors are now numerically stronger than in the old insurance committees, and can be drawn from a wider selection of areas. For the first time they meet and confer with the councillors, who in another place are responsible to the people for health provision. The design is one which can, and eventually will, provide great and growing opportunity for professional guidance of, and influence on, the developing pattern of the new service.

THE TEACHING HOSPITAL

The Act gives the teaching hospitals opportunities which, if used wisely and imaginatively, augur well for the future of medicine in general, and of medical education in particular. All hospitals will be less susceptible to those financial anxieties which changing economic circumstances bring in their train; equipment and facilities will be more closely related to demonstrable needs and less dependent on the whims of the generous. But it is especially in the solution of two closely related problems for the teaching hospitals that the new order opens the way.

Firstly, in adjusting the internal pattern of its services so that the demands of undergraduate teaching may best be met. In the past few decades the increasing complexity of diagnosis and treatment has been reflected in an increasing compartmentalism; the teaching hospital has too often become a collection of highly specialised units, and undergraduate training has correspondingly suffered. The future offers opportunities for experiment: for example, in the design of the undergraduate teaching hospital; the distribution of beds; the provision of "admission" wards through which most patients will pass before they are directed to the medical, surgical, or specialist services; the association of model health centres with the work of the hospital; and a host of other issues.

Secondly, teaching hospitals have hitherto remained too often isolated both from each other and from non-teaching hospitals. The inadequate use, for teaching, of the staff and facilities in non-teaching hospitals has been rightly criticised. Clearly all suitable resources in both groups of hospitals should be tapped for both undergraduate and postgraduate teaching. To this end the term "non-teaching" hospital should be abolished, and two desiderata promoted:

(1) There must be a large measure of common staffing between both groups of hospitals. Special units will be placed where they are best suited, and the needs of the undergraduate will not be sacrificed to those of the member of a teaching hospital staff who is developing such a unit.

(2) There must be set up non-statutory committees, representing three interests—the university medical school, the regional board, and the board of governors—whose prime concerns will be how to ensure this common staffing and how and where can best be provided the clinical requirements of the medical school for its undergraduates and postgraduates.

The harmonious working of such a committee, and the personal contacts it would permit, would play a most useful part in breaking down any barriers which might arise between regional and teaching hospitals. Nothing will militate more against the success of the projected hospital service than its inheritance of antagonisms analogous to those which so often existed in the past between teaching and non-teaching hospitals, and between voluntary and municipal hospitals.

In a unified hospital system, the regional and teaching hospitals have complementary rôles: both will take part in teaching; both will, it is hoped, provide the highest standards of service. But each will so model itself that it can best fulfil its special purpose for the general good.

THE REGIONAL BOARD

Most regional boards have now completed their first task—the grouping of hospitals and the selection of committees of management ready to take over on the appointed day. Much more "domestic" spade-work lies before them. Work of this type is all-important if the hospitals are to be efficiently and economically administered. For the most part such problems are the

NATIONAL HEALTH SERVICE

A Message to the Medical Profession from the Minister of Health

ON July 5 we start, together, the new National Health Service. It has not had an altogether trouble-free gestation! There have been understandable anxieties, inevitable in so great and novel an undertaking. Nor will there be overnight any miraculous removal of our more serious shortages of nurses and others and of modern replanned buildings and equipment. But the sooner we start, the sooner we can try together to see to these things and to secure the improvements we all want.

On July 5 there is no reason why the whole of the doctor-patient relationship should not be freed from what most of us feel should be irrelevant to it, the money factor, the collection of fees or thinking how to pay fees—an aspect of practice already distasteful to many practitioners. Yet it has been vital, if this is to be the new situation, to see that it did not carry with it either any discouragement of professional and scientific freedom or any unfair worsening of a doctor's material livelihood. I sincerely hope and believe we have secured these things. If we have not, we can easily put that right.

The picture I have always visualised is one, not of "panel doctoring" for the less well-off, not of anything charitable or demeaning, but rather of a nation deciding to make health-care easier and more effective by pooling its resources—each sharing the cost as he can through regular taxation and otherwise while he is well, and each able to use the resulting resources if and when he is ill. There is nothing of the social group or class in this; and I know you will be with me in seeing that there does not unintentionally grow up any kind of differentiation between those who use the new arrangements and those who, for any reason of their own, do not. Let this be a truly national effort. And I, for my part, can assure you that I shall want vigilantly to watch that your own intellectual and scientific freedom is never at risk of impairment by the background administrative framework, which has to be there for organising purposes, but in which your own active participation is already secure.

In this comprehensive scheme—quite the most ambitious adventure in the care of national health that any country has seen—it will inevitably be you, and the other professions with you, on whom everything depends. My job is to give you all the facilities, resources, apparatus and help I can, and then to leave you alone as professional men and women to use your skill and judgment without hindrance. Let us try to develop that partnership from now on.

It remains only to wish you all good luck, relief—as experience of the scheme grows—from your lingering anxieties, and a sense of real professional opportunity. I wish you them all, most cordially.

ANEURIN BEVAN.

The Opportunities

In developing the new service members of the medical profession are already playing a large part. We have asked six of them to say something about the aims of the boards or committees to which they belong.

MANAGEMENT COMMITTEE

Some people still think that the fiery cross will go round the professional clans on the fatal night of July 4–5. They are mistaken. Nurse Robertson will drink her cup of tea, and Dr. Hendry will take his white coat down from the peg as usual. Mrs. Richard Brown will lie placidly in bed, at Roxton Cottage Hospital, on Monday as she did on Sunday; and her new baby will be just as wonderful.

When the hospital management committee meets, the first thing that its members have to learn is to extend their loyalty from the unit to the group, in the firm belief that the group will reward their faith by offering wider opportunities for service to the sick. The second point to remember is that they do not represent any one hospital or any single interest. Most of them are local folk, sensitive to the traditions and prejudices of their own place. That is as it should be; but it must not allow them to turn the management committee into just one more link in the *long chain of administration*. The job of the committee is not to delegate, but to manage the hospitals of its group. If it fails to bring about this coördination, it fails altogether.

A hospital group is not a machine; *it is a form of human society woven together by the threads of human relationships.* In the balance it is the persons that count, and the cooperation of medical, nursing, and technical staff in the work of the group is far more important than mere administrative tidiness. The composition of the hospital group under one management varies greatly: some groups contain several general hospitals with full-time directors and professional staff; others have a special hospital with national as well as regional obligations; and others again support one big parent hospital surrounded by a family of little ones. It is of great importance that the staff should get together quickly and study how they can best work as a team, so as to render the most effective service to the group as a whole. There will be one main committee to balance the various needs and serve them *in a rational way, and there will be one staff* to help where help is most required. This excellent X-ray apparatus at Loxton will serve three small hospitals comfortably and in this way all of them will have the benefit of Dr. Martin's wide experience in radiology. The three radiographers also will be able to arrange their duties so as to get regular time off, without interrupting the service. *That dangerous little set* at Poxton Cottage Hospital can now be dismantled, and the room it clutters up can make a useful addition to the outpatient department. We may even ask the regional hospital board to pension off the poor old isolation hospital at Moxton and transfer our patients to the splendid modern wards at Foxton. The first step *is to bring together and to simplify.*

There are pitfalls to be avoided. The people of any district have a pride and delight in their own hospital. It is right that they should continue to give support, both personal and financial, to the institution which they have built up, perhaps over many years. There ought to be no conflict between the unit and the group. All places for the care of the sick have needs that budgets cannot satisfy; some of these needs cost money to fulfil—the delicate amenities such as flowers and special decorations that mean so much to the sick, and in

BRITISH MEDICAL ASSOCIATION

In 1914 the British Medical Association met at Aberdeen; and its first full meeting after the first war was held, in 1920, at Cambridge. In 1939 the meeting was again at Aberdeen; and now the second round has been completed by the first full meeting since 1939 which opened last week at Cambridge.

PRESIDENT'S ADDRESS

In his presidential address, on the Changing Face of Medicine, Sir LIONEL WHITBY measured the past against the future. He was able to show that State control is no new venture, for about 1948 B.C. King Hammurabi, of Babylon, issued an edict whereby medical practice was governed by a code which was published in every market-place. Egyptian medicine was governed by the code of the Ebers Papyrus; whilst the books of Leviticus and Deuteronomy described a fine example of public-health regulations under central control. Nor was the "closed shop" principle new. For many centuries the physicians in this country clung to their monopoly, stubbornly refusing the claim of the barber-surgeons to prescribe internal remedies.

In more recent times State intervention had been hastened by three wars in the first half of this century. The examination of recruits for the Boer War revealed appalling unfitness, which led to the establishment, in 1907, of a school medical service, and subsequently of maternity and child-welfare services and the National Health Insurance scheme. The Ministry of Health was born of the turmoil of the 1914–18 war; while in the late war the Emergency Medical Service afforded experience for the foundation of the National Health Service.

It had to be admitted that the State's growing participation in medicine was not without advantages. Modern team-work provided, organised, and financed by the State could do much to exploit and perfect a fundamental discovery: witness the speed with which money and coördinated work brought penicillin into the realm of everyday therapeutics. But nationalisation must inevitably restrict individualism; and

> "let us hope that there will always be elbow-room for a man to work out his own ideas, to be outspoken in criticism and in debate, and to be free from unnecessary restrictions, regulations, and regimentation. Let us hope that men may still be inspired to undertake work for the love of it."

Representative Meeting

The representative body assembled on June 25, under the chairmanship of Dr. J. B. MILLER. It was agreed that next year's meeting should be held at Harrogate, under the presidency of Dr. C. W. Curtis Bain. Dr. Peter Macdonald and Prof. R. M. F. Picken were elected vice-presidents in appreciation of their exceptional services to the association.

WORLD MEDICAL ASSOCIATION

Dr. H. A. PRIDHAM (Dorset) reported that the World Medical Association now had offices in New York. A general assembly to be held at Geneva in September would consider a wide range of subjects, including medical ethics, social security, postgraduate training, resettlement of refugee doctors, secret remedies, and exchange of visits between doctors in different lands.

NO WITCH HUNT

Dr. H. GUY DAIN, chairman of the council, said that since the representatives' last meeting the Negotiating Committee had set up subcommittees concerned with general practice, specialist practice, compensation, and other problems.

Dr. A. C. E. BREACH (Bromley) moved that, in view of the doubts and criticisms among some doctors, the council should be asked to set up a committee to investigate the conduct of the profession's case this year. The purposes, he suggested, should be to learn what really happened, and to get information which would be useful in the future. Dr. J. B. W. ROWE (Harrow) agreed that many doctors were dissatisfied with the recent conduct of affairs, and he thought that such a committee's report might be useful in the future; it should not be forgotten that the Socialist party still adhered to the idea of a whole-time salaried service. Dr. DAIN retorted that the motion was founded on suspicion; the implication was that he and the council had not disclosed information, and this he refuted absolutely. "There is nothing which the committee can disclose which is not already fully known to you." Moreover, representatives had taken responsibility for each step. The real purpose of the resolution was to discover what differences existed among representatives; but they had agreed to cooperate in the new service, and it was for them to keep the association firmly on its feet. The proposed investigation would have a harmful effect on public and medical opinion and on the standing of the association. Dr. E. A. GREGG (St. Pancras) urged that there should be no heresy hunt. Only bad feeling, resentment, and unpleasantness could come from the setting up of this committee. Mr. A. DICKSON WRIGHT (Marylebone) was puzzled to know why the chairman of council and Dr. Gregg were so vociferously opposed to the establishment of the committee. There was, he thought, mystification among the profession and the public; and even as a member of the council he had been surprised at the sudden collapse of opposition. At the centre it was said that the rot had started at the periphery; but at the periphery it was asserted that it had begun at the centre. Dr. C. F. MAYNE (Plymouth) pointed out that the council had been given a free hand; and Dr. S. WAND (Birmingham) pleaded for unity which, he said, implied standing by the majority vote. Dr. Breach's resolution was rejected.

REMUNERATION

Dr. P. J. GIBBONS (Liverpool) called for negotiation of terms of service for all medical hospital staffs not covered by the Spens report. This was accepted after Dr. DAIN had explained that the council intended to examine the remuneration of all doctors in the light of the two Spens reports; the intention was to see how the remuneration of all—including those in the Public Health Service, the Armed Forces, and the Colonial Service—could be related to the recommendations in these reports.

Dr. R. G. ANDERSON (Gloucestershire) demanded adequate remuneration of general practitioners as a vital factor in maintaining and improving the quality of medical practice. Dr. O. C. CARTER (Bournemouth) said that the Spens Committee on the remuneration of practitioners, of which he had been a member, had taken 2000 as the desirable maximum number of patients; and as soon as more doctors were available, remuneration should be determined according to a lower maximum than the present 4000. It was important, moreover, to see that special awards were correctly allocated to outstanding practitioners; the fact that a doctor had 4000 patients on his books did not necessarily mean that he was outstanding. Finally, it was necessary to make natural concern of the lay members of boards. To the medical members, however, more fascinating problems loom ahead, and it is clear that the Act has conferred upon us as a profession great responsibilities for the exercise of imagination and leadership. These responsibilities are ours alone, and we must not fail to rise to the occasion. Regionalisation, in essence, is the diffusion throughout a region of a complete specialist service based on the hospitals, and the integration of all fields of specialist practice in a coherent whole. We are primarily concerned with the standards of the science and practice of medicine. Such regionalisation cannot be achieved by any so-called bureaucratic plan involving regimentation and direction of the members of a specialist corps within a region; nor, as I see it, does the Act suggest or even encourage such notions. One master there must be in the final analysis—the Treasury—which implements the ideas of the nation on the amount to be spent on the hospital services. To this disciplinary check we must all bow. But regional boards, boards of governors of teaching hospitals, and committees of management all contain large quotas of medical members; and advisory medical committees, both in hospitals and outside hospitals, will soon be set up. As a profession we are in a more powerful position than ever before. If we grasp the opportunities presented to us the hospital services of the future will bear the imprint of the ideas and standards of our free and learned profession. July 5 in the hospital world in this country is not the Loss of Independence Day, but, as President Woodrow Wilson long ago said of July 4, "This is Interdependence Day."

THE LOCAL MEDICAL COMMITTEE

So that the transition from National Health Insurance to the National Health Service should be smooth, the Minister of Health said some months ago that he would recognise the existing local medical and panel committees as "local medical committees" for the purposes of the new Act. As election to these committees was suspended during the war, many have been preparing themselves for their new duties by fresh elections and sometimes by revision of their constitution.

Many of the duties so far undertaken are not new; they had their parallel under National Health Insurance. It was no novelty to older members of the committee to be asked to scrutinise, amend, and approve schemes for allocation, distribution, and mileage; nor did they find it hard to accept membership of such familiar bodies as the medical service committee (dealing with complaints against doctors) and the allocation committee (dealing with patients unable themselves to secure acceptance on any doctor's list), or even of the executive council itself. For though the council offers the local medical committee a larger part to play, it remains the old insurance committee writ large. What are new are the opportunities now being provided for linking the activities of the local medical committees with those of bodies such as the statutory health committees of the local health authority, the hospital management committees, and the regional committees for consultants and specialists. In some local medical committees, also, reciprocal cooption of representatives from such fields as obstetrics, ophthalmology, and preventive medicine is being discussed. Through these new links the local medical committees are finding new means of integrating the different parts of the growing service, and particularly of ensuring that at no level shall the needs of the general practitioner be unknown, nor his advice unsought.

If the load is to be spread and the work well done, such diverse calls as these demand that in many areas there should be larger committees, meeting more frequently than has usually been necessary in the past. On the whole the extra work is being readily undertaken. In my own committee, meetings are well attended: each new scheme or fresh regulation is critically examined; the many nominees required for service with other bodies are forthcoming in more than adequate number; and altogether there is good reason to hope that, even though the infant service does not escape all teething troubles, these inevitable maladies will at least be detected and corrected without either undue delay or disaster.

THE MEDICAL OFFICER OF HEALTH

The great debate is over. Some questionings and some doubts remain, but the fundamental question is answered. It has been a necessary phase, which has secured to the profession its essential freedoms. Now the tumult and the shouting dies and the hum of preparation gains in intensity. What are the opportunities as they present themselves to the eyes of a medical officer of health? His gaze may at the moment be somewhat myopic—no section of the profession indeed has been more drastically reoriented—and focused on his departing glories rather than on the future; but his work, one hundred years of struggle towards the greatest good of the greatest number, both needs and develops the philosophic mind, and he has the consolation of seeing the preventive idea now dominating the whole of British medicine. He has the still greater consolation of an important place in one of the three great branches of the new service. Here he can be of real value in fostering the team-work which should be the keynote.

Coöperation, not competition. Not at any rate competition for the most patients and the biggest income, but rather for the best standard of service, whether in consulting-room, health centre, or hospital. And coöperation in placing knowledge and technical resources at the disposal of any patient who needs them. This is the greatest of the many opportunities the Act presents. Nothing less must be the goal of those who join. Those who stay out will miss something. They may be less pressed; the amount of time they can give to individual patients may be greater; but the stage on which they perform will be smaller. Attending to the medical needs of 40 million people is a big and worth-while job. It will mean pressure on those providing the service, it will certainly involve frustrations and vexations, but it will give satisfaction—not least the satisfaction of working in teams.

The profession can mould the service. On every piece of administrative machinery it is well represented and on some it is dominant. Committee work can be boring, but it is indispensable and the profession's opportunity is as great as its responsibility. Traditions must be made, and policy guided by the accumulated skill and wisdom of the profession. Its committee men must do a good job.

The profession must also examine its rôle in health education. Much of what now passes under that name only produces disease consciousness. That in turn means fear. It is surprising how large a part fears play in modern life. We have it that the right kind is the beginning of wisdom, and the doctor can perhaps discourage some of the others. The effort, one imagines, will have to concentrate more on the individual than on the mass, but there will be scope for it in the new service. Even within the profession itself there are some of these fears and bogies that we might well start to exorcise.

The nation has recently lived triumphantly through its finest hour. We are all a bit tired and the road to the new service will be uphill at the beginning; but the vista at the top will match the vision at the foot. Pioneering has never been easy, but the profession now has its chance. Grumbling in traditional style, it is also getting ready to get on with the job. The shades of Simon, Budd, Farr, Hunter, Lister, Osler, Macewen, Robert Jones, Dawson, and others of the elect must be watching with interest. And so must that of Chadwick.

the profession there was a tremendous body of opinion against forming a union. Dr. DORIS ODLUM (Bournemouth) held that among the necessary modifications was redistribution of geographical representation to conform with the new regions.

Dr. J. N. P. DAVIES (Uganda) intervened to tell of his experience of a complete service under government control. If, he said, representatives knew what had gone on in the Colonial Empire for 25 years, they would see the need for a union. Governments were now conditioned to collective bargaining, and this had to be backed up from time to time by strong action. In a government service conditions were never permanent; they were liable to be changed without negotiation.

Dr. GREGG recalled that he had belonged to a medical trade union but had left it. Applying to the T.U.C. with claims from this union, he had been told that only one body was recognised as representing doctors—namely, the B.M.A. He was now more than ever impressed with the Government's attitude to the association. There had been no hint, outside the ranks of the association, that it was not strong enough for its new tasks. He had eventually resigned from the union because he had found there destructive criticism of, and rivalry with, the B.M.A.

Dr. DAIN agreed that a special committee should consider modifications in the constitution, and that a representative meeting should be called as soon as the committee's investigation was completed. Satisfied with this promise, the meeting passed to the next business.

CONSULTANTS AND SPECIALISTS' COMMITTEES

Mr. A. M. A. MOORE recalled that the consultants and specialists' committee (of which he is chairman) had gained the council's approval for a proposal to establish regional committees to protect specialists' interests. Medical staff committees were to elect members of these regional committees. Each of the 19 regional committees would appoint 2 representatives to the central committee, whose total membership would be 72. The latest conference convened to consider this plan had been attended by medical representatives of the staffs of non-teaching hospitals and of the provincial teaching hospitals. Previously, fear had been expressed by the teachers that they might be outvoted by the non-teachers; but at this last meeting the non-teachers had agreed that, in view of the urgent need, they would abandon their advantage in numerical superiority, and would accept equal representation with teachers on the central committee. In the regional committees, however, the ratio between teachers and non-teachers should be decided by local conditions. These regional committees should have the greatest possible autonomy within the machinery of the B.M.A. In every region meetings were to be held in order to set up interim committees to operate until the permanent organisation was established in a year's time. The recent conference had urged that the central committee should elect its own chairman who should be an ex-officio member of the B.M.A. council.

Mr. N. ROSS SMITH (Bournemouth) moved that the central committee should be autonomous. Specialists, he added, feared that they might be outvoted in the association; and it was essential to allay this fear since otherwise they might form an outside body, which would perpetuate the division among themselves and between themselves and other doctors. Dr. DAIN accepted the suggestion that the central committee should have the same status and independence as the Insurance Acts Committee. Mr. HUGH CARSON (Birmingham) reported that in his area the sentiment of specialists was that the committee should be separate from the association; and he believed that this feeling prevailed elsewhere. The Bournemouth resolution was carried.

The meeting also agreed that the central committee should elect its own chairman who should thus become a member of the council.

Dr. PRIDHAM said that no organisation other than the B.M.A. could supply the machinery needed by consultants and specialists, who could come into partnership with the association as had the Insurance Acts Committee. Mr. ERIC STEELER (Marylebone) said that consultants feared a split in their ranks, one section turning to the Royal Colleges and the other to the association. A large majority of his constituents thought that the colleges should have their support. Dr. MAYNE, on the other hand, reported that in his part of the country there was strong support for an organisation associated with the B.M.A. Why had the colleges suddenly emerged from their academic sphere? Their influence would be greater if they remained apart from the hurly-burly of political activities. Mr. R. L. NEWELL (Manchester) pointed out that the colleges offered no peripheral organisation; he refused to submit to such a state.

The meeting approved the plan put forward by Mr. Moore on behalf of the B.M.A. committee.

Dr. DAIN said that by this plan consultants and specialists would be assured of an autonomous machine, free from control by any central caucus. The plan would be put into immediate operation.

CERTIFICATION

Dr. WAND, chairman of the general-practice committee, reminded the meeting that a committee, which included representatives of the association, had been set up by the Government to consider certification. The meeting supported Dr. Wand's resolution that a practitioner should be required by the regulations to furnish patients, receiving treatment under the Act, only with such certificates as were necessary to claim (*a*) sickness and disablement benefit, (*b*) essential surgical appliances, and (*c*) special treatment.

HEALTH CENTRES

Dr. A. TALBOT ROGERS (Bromley), chairman of a special committee set up last year to report on health centres, announced that the committee's findings had just been placed before the council. The committee was satisfied that the time was ripe for experiment with health centres; there was knowledge enough for a start to be made without risk of serious mistakes. He believed that a central committee should watch over experiments, give advice, and collect experience. Several representatives spoke against undue haste; and the following resolution, proposed by Dr. D. S. SAKLATVALA (West Bromwich) was passed as a reference to council:

> That this meeting would view with the greatest dismay any hasty widespread starting of health centres, and is of opinion that the Minister should sanction at the present time only carefully chosen experimental types in properly selected areas, and that he should ensure that the data collected and the lessons learned from these experimental centres should be made generally available to local health authorities and executive councils as soon as possible.

CORONERS' ACTS

Dr. R. FORBES, chairman of the Coroners' Acts committee, secured approval for recommendations made by a special committee set up in 1946 to report on the medical aspects of these Acts. The following are among the recommendations:

> (1) (*a*) That the most suitable persons for appointment to coronerships are those with dual qualifications in medicine and law; (*b*) that coroners' jurisdictions should be merged in natural areas large enough to warrant the appointment of suitably qualified coroners.

special provision for doctors in areas where the number of chronic sick was abnormally high.

Dr. W. Woolley (Bristol) argued that, for future protection, representatives should make sure that the Minister of Health fulfilled his promise to implement the Spens report. Dr. Wand agreed that the "spread" had not been obtained; but attainment of it was difficult with payment by capitation fees, and it might be wise to leave this question in abeyance for a short time. He hoped that representatives would give their attention to the betterment factor, which seemed insufficient to him. Dr. R. B. McColl (Denbigh and Flint) reported that in his part of the country some doctors would have to be content with lists of 1200–1500; there, he said, the possibility of remuneration by a sliding scale had been mooted.

Dr. Dain reminded representatives that the Minister had given an assurance that as soon as the service started they would be free to raise the question of the betterment factor through the appropriate Whitley council. Except that the full range was not covered, the Minister's offer had assured full implementation of the Spens report. The average list would be of about 2000; only the very able and those geographically well situated would be able to take 4000. He argued that doctors in rural areas with considerably less than 4000 patients would fare well enough with remuneration from the capitation pool and the special inducements fund, and with ordinary and special mileage allowances; and soon the betterment factor might be increased. The idea of a sliding scale, by which those with most patients got least reward, was pernicious; and he preferred that special protection should be given to the rural practitioner. The Gloucestershire motion was carried.

Dr. J. S. Ross (East Herts), moving that the question of remuneration of practitioners on the staffs of cottage hospitals should be brought to the notice of the Minister, said that there was a good case for their proper remuneration. This resolution also was carried.

MILEAGE

Dr. R. G. Gemmell (Dumfries and Galloway) won support for a resolution that the Minister of Health should be pressed to grant an adequate mileage fee for rural practitioners. After Dr. Dain had described the proposed mileage arrangements, which he thought adequate, Dr. O. G. Barber (Mid Essex) suggested that capitation fees should be determined in units up to a maximum of 4000. In towns each patient would count as 1 unit; in some rural areas each would count as $1^1/_2$ units, while in others each might count as 2 units.

MATERNITY MEDICAL SERVICE

Dr. W. D. Steel (Worcester and Bromsgrove) proposed the abolition of local obstetric committees. How, he asked, was efficiency to be estimated by a committee consisting of 1 obstetrician, 1 medical officer of health, and 2 general practitioners? Dr. D. L. S. Johnston (Halifax) thought that the best solution would be for new entrants to the service to undertake three months' postgraduate training in midwifery, to qualify them to take part in the midwifery service. In his area no-one was willing to sit in judgment on his colleagues; owing to the difficulty of adjudication established practitioners should be allowed to continue midwifery. Dr. Dain pointed out that originally there was no place for the practitioner in the new midwifery service, except when he was called in by the midwife. Now, however, the doctor who was doing sufficient midwifery and wanted still to do it could be entered on the list; and time would show whether he continued to do enough. The difference in fees between approved and non-approved practitioners was determined by difference in the extent of service: the five-guinea fee was for attendance at the confinement, while the seven-guinea fee was for antenatal and postnatal attention in addition to, sometimes, attendance at the confinement. The Worcester motion was rejected.

PHARMACEUTICAL SERVICES

Dr. Ross (East Herts) gained support for a resolution that patients who obtained medical service outside the scheme should not have to forgo the benefits of the pharmaceutical service. Dr. Dain said that the Minister had refused to concede this point, arguing that he must retain some control over the ordering of drugs. It was hoped that such drugs as insulin might be obtained through hospitals by private patients. The whole question was still under review.

MEDICAL REPRESENTATION ON COMMITTEES

Dr. Barber proposed that legislation should be introduced so that the appointment of doctors to statutory bodies should be by democratic election by the profession and not by the Minister's nomination. Dr. Dain pointed out that this right had already been gained in respect of executive councils. As regards other bodies, the Minister was bound to consult, but he consulted many organisations in addition to the B.M.A. Dr. Dain thought that the association might publish the names of its chosen nominees; Dr. Barber's resolution was carried.

VACCINATION

Dr. J. W. McCarthy (Hendon) called for the restoration of compulsory vaccination. What he feared most was encephalitis among those vaccinated for the first time during a smallpox outbreak. The meeting preferred, however, a more modest resolution by Mr. A. Lawrence Abel (Marylebone), which demanded constant vigilance, frequent review of the position, and a reminder to the Minister that there might be a serious outbreak in a few years. Dr. J. M. Gibson said that in his industrial area not more than 25% of infants had been vaccinated, owing to the conscience clause. Results would be better with a voluntary system.

COMPENSATION TO RADIOLOGISTS

Dr. A. Campbell (Edinburgh) drew attention to the possible plight of private radiologists in the new service, for they now had expensive equipment and many operators. Dr. Dain explained that in the service there would be room for every radiologist; and the Minister was prepared to take over at proper valuation the equipment of those wishing to enter the service.

A TRADE UNION ?

Dr. J. A. Gorsky (Westminster and Holborn) proposed that the association should explore the possibility of setting up a body equivalent to a trade union. There was no doubt in his mind that the association, as a body registered under the Companies Act, was not able to turn itself into a trade union. He argued, however, that doctors' contracts were of service rather than for services, and that, this being so, they could form themselves into a union.

Dr. J. O. McDonagh (Perth) said that his division, recognising that the association could not apply its funds to the purposes of a union, suggested the formation of a parallel body. Under the new conditions doctors were simply another group of workers; and in future the association's bargaining position would not be strong enough. Dr. R. P. Liston (Tunbridge Wells) thought that the name "medical guild" would come more easily to the lips of doctors than "trade union." The urgency of the need was underlined by events in the recent crisis, when it had been necessary to set up an Independence Fund as an entity separate from the association. Dr. M. W. Gardner (Brighton) said that in the profession there was a tremendous body of opinion against forming a union. Dr. DORIS ODLUM (Bournemouth) held that among the necessary modifications was redistribution of geographical representation to conform with the new regions.

Dr. J. N. P. DAVIES (Uganda) intervened to tell of his experience of a complete service under government control. If, he said, representatives knew what had gone on in the Colonial Empire for 25 years, they would see the need for a union. Governments were now conditioned to collective bargaining, and this had to be backed up from time to time by strong action. In a government service conditions were never permanent; they were liable to be changed without negotiation.

Dr. GREGG recalled that he had belonged to a medical trade union but had left it. Applying to the T.U.C. with claims from this union, he had been told that only one body was recognised as representing doctors—namely, the B.M.A. He was now more than ever impressed with the Government's attitude to the association. There had been no hint, outside the ranks of the association, that it was not strong enough for its new tasks. He had eventually resigned from the union because he had found there destructive criticism of, and rivalry with, the B.M.A.

Dr. DAIN agreed that a special committee should consider modifications in the constitution, and that a representative meeting should be called as soon as the committee's investigation was completed. Satisfied with this promise, the meeting passed to the next business.

CONSULTANTS AND SPECIALISTS' COMMITTEES

Mr. A. M. A. MOORE recalled that the consultants and specialists' committee (of which he is chairman) had gained the council's approval for a proposal to establish regional committees to protect specialists' interests. Medical staff committees were to elect members of these regional committees. Each of the 19 regional committees would appoint 2 representatives to the central committee, whose total membership would be 72. The latest conference convened to consider this plan had been attended by medical representatives of the staffs of non-teaching hospitals and of the provincial teaching hospitals. Previously, fear had been expressed by the teachers that they might be outvoted by the non-teachers; but at this last meeting the non-teachers had agreed that, in view of the urgent need, they would abandon their advantage in numerical superiority, and would accept equal representation with teachers on the central committee. In the regional committees, however, the ratio between teachers and non-teachers should be decided by local conditions. These regional committees should have the greatest possible autonomy within the machinery of the B.M.A. In every region meetings were to be held in order to set up interim committees to operate until the permanent organisation was established in a year's time. The recent conference had urged that the central committee should elect its own chairman who should be an ex-officio member of the B.M.A. council.

Mr. N. ROSS SMITH (Bournemouth) moved that the central committee should be autonomous. Specialists, he added, feared that they might be outvoted in the association; and it was essential to allay this fear since otherwise they might form an outside body, which would perpetuate the division among themselves and between themselves and other doctors. Dr. DAIN accepted the suggestion that the central committee should have the same status and independence as the Insurance Acts Committee. Mr. HUGH CARSON (Birmingham) reported that in his area the sentiment of specialists was that the committee should be separate from the association; and he believed that this feeling prevailed elsewhere. The Bournemouth resolution was carried.

The meeting also agreed that the central committee should elect its own chairman who should thus become a member of the council.

Dr. PRIDHAM said that no organisation other than the B.M.A. could supply the machinery needed by consultants and specialists, who could come into partnership with the association as had the Insurance Acts Committee. Mr. ERIC STEELER (Marylebone) said that consultants feared a split in their ranks, one section turning to the Royal Colleges and the other to the association. A large majority of his constituents thought that the colleges should have their support. Dr. MAYNE, on the other hand, reported that in his part of the country there was strong support for an organisation associated with the B.M.A. Why had the colleges suddenly emerged from their academic sphere? Their influence would be greater if they remained apart from the hurly-burly of political activities. Mr. R. L. NEWELL (Manchester) pointed out that the colleges offered no peripheral organisation; he refused to submit to such a state.

The meeting approved the plan put forward by Mr. Moore on behalf of the B.M.A. committee.

Dr. DAIN said that by this plan consultants and specialists would be assured of an autonomous machine, free from control by any central caucus. The plan would be put into immediate operation.

CERTIFICATION

Dr. WAND, chairman of the general-practice committee, reminded the meeting that a committee, which included representatives of the association, had been set up by the Government to consider certification. The meeting supported Dr. Wand's resolution that a practitioner should be required by the regulations to furnish patients, receiving treatment under the Act, only with such certificates as were necessary to claim (*a*) sickness and disablement benefit, (*b*) essential surgical appliances, and (*c*) special treatment.

HEALTH CENTRES

Dr. A. TALBOT ROGERS (Bromley), chairman of a special committee set up last year to report on health centres, announced that the committee's findings had just been placed before the council. The committee was satisfied that the time was ripe for experiment with health centres; there was knowledge enough for a start to be made without risk of serious mistakes. He believed that a central committee should watch over experiments, give advice, and collect experience. Several representatives spoke against undue haste; and the following resolution, proposed by Dr. D. S. SAKLATVALA (West Bromwich) was passed as a reference to council:

> That this meeting would view with the greatest dismay any hasty widespread starting of health centres, and is of opinion that the Minister should sanction at the present time only carefully chosen experimental types in properly selected areas, and that he should ensure that the data collected and the lessons learned from these experimental centres should be made generally available to local health authorities and executive councils as soon as possible.

CORONERS' ACTS

Dr. R. FORBES, chairman of the Coroners' Acts committee, secured approval for recommendations made by a special committee set up in 1946 to report on the medical aspects of these Acts. The following are among the *recommendations*:

(1) (*a*) That the most suitable persons for appointment to coronerships are those with dual qualifications in medicine and law; (*b*) that coroners' jurisdictions should be merged in natural areas large enough to warrant the appointment of suitably qualified coroners.

(2) That every coroner should keep adequate records, of which copies should be obtainable by interested persons on payment of a fee.

(3) That a consultative committee be set up to consider matters affecting the duties of coroners.

(4) That all inquests be in public; that in the case of an inquest on a "suicide" the press be prohibited from publishing an account of the proceedings and permitted only to publish the fact that an inquest has been held, the name and address of the deceased, and a verdict that the deceased died by his own hand.

(5) That early action should be taken to provide a full post-mortem service on a nation-wide scale.

A further recommendation—that as an interim measure urgent consideration should be given to mobilising pathologists and enabling them to travel to the various outlying mortuaries with fully equipped motorised laboratories—was withdrawn and referred to council after several representatives had objected that this proposal was unreasonable.

ELECTIONS

Dr. E. A. Gregg was elected chairman and Dr. J. A. Brown vice-chairman of the representative body. Mr. A. M. A. Moore was elected treasurer in succession to Dr. J. W. Bone. At the annual general meeting Sir Hugh Lett, the retiring president, inducted as president Sir Lionel Whitby.

Special Articles

HOSPITAL ADMISSIONS IN METROPOLITAN REGIONS

THE Metropolitan regional hospital boards have circulated a letter to local authorities and executive councils giving details concerning the admission of patients to hospitals in their area. As was explained in our leading article of June 19 (p. 951), the boards intend that as far as possible admissions shall be arranged direct between the doctor and the hospital. Where a doctor cannot secure a patient's admission to the hospital of his choice he should apply to the Emergency Bed Service (E.B.S.) who will try to find a suitable vacancy and if successful will arrange for the patient's transport to hospital. If free treatment is desired in any hospital not administered under the National Health Service, application must be made through the regional hospital board. A doctor representing the boards will be attached to the E.B.S.

Arrangements are being made to provide local admission centres, where necessary, throughout the regions. The establishment of these centres will take time and it will not be possible to complete arrangements for all areas by July 5. The E.B.S. has appointed officers to organise the admission system throughout the four metropolitan regions and these officers will visit all hospitals as soon as possible. Information concerning these centres will be issued locally.

Acute Sick.—Present procedure will be generally unchanged. Doctors may apply for admission direct to the hospital of their choice or through the E.B.S.

Non-urgent Cases.—Hospitals will maintain waiting-lists for non-urgent cases as at present, and will notify patients direct when a bed is available.

Chronic Sick.—There are now a large number of unstaffed beds for patients in this category and it is unlikely that additional nurses for these beds will be forthcoming for a considerable time. It will be necessary, therefore, for rigid selection to be exercised as regards admissions. Where the case is one of medical urgency the practitioner will apply to the nearest general hospital, and, if no bed is available, will apply to the E.B.S. for a vacancy. If the predominant need for admission is on social grounds, the E.B.S. will make arrangements through the appropriate medical officer of health for the home conditions to be investigated. If the case is not urgent the patient's name will be placed on the waiting-list of the nearest suitable hospital.

Infectious Diseases.—The present admissions procedure in the County of London area will be undertaken by the E.B.S., to which applications for admission should therefore be made. Uncomplicated cases of measles, chicken-pox, scarlet fever, german measles, or mumps will not be admitted to infectious disease hospitals unless the medical officer of health of the area supports the applications for admission, so in such cases applications should be made through the medical officer of health. Outside the County of London, doctors should apply direct to their nearest fever hospital or, if they cannot obtain a bed in this way, they should apply to the E.B.S.

Maternity.—Maternity patients will normally be admitted either on medical or social grounds. In the case of the former admission will be arranged between the practitioner and the hospital concerned; in the latter, a statement on social conditions will be required from the local health authority. In cases of obstetrical emergency application can be made to the E.B.S.

Mental Cases.—Mental cases requiring urgent admission will be dealt with by the duly authorised officer (who replaces the relieving officer), particulars of whom can be obtained from the local health authority. These officers will arrange for the admission of patients to mental observation wards or mental hospitals. Arrangements for the admission of voluntary patients under the Mental Treatment Act should be made direct with the appropriate mental hospital.

Mental Deficiency Act Cases.—Local health authorities remain responsible for the initial action; they should continue to arrange admissions direct with those mental-deficiency institutions within the National Health Service which they now use. If free treatment in a mental-deficiency institution outside the National Health Service is desired, application must be made to the regional hospital board and not to the institution.

Tuberculosis.—The E.B.S. will not be concerned with tuberculous cases save to arrange admission of emergencies—e.g., hæmoptysis—to a general hospital if required to do so. All recommendations for admission of tuberculous patients will normally come to the regional hospital board through the tuberculosis officers. Practitioners will refer all cases to the tuberculosis officer, who will make the appropriate recommendation for sanatorium or other treatment. No application for sanatorium treatment should be made to the E.B.S.

Convalescence.—Inquiries concerning convalescent beds may be made to the E.B.S. Further details will be issued to hospitals shortly.

The London offices of the Emergency Bed Service are at 10, Old Jewry, E.C.2, and the telephone number is Monarch 3000.

THE STRESS DISEASES

SIR STAFFORD CRIPPS AT ROFFEY PARK

OPENING the new training and research department at Roffey Park Rehabilitation Centre, Sussex, on June 12, Sir STAFFORD CRIPPS, Chancellor of the Exchequer, spoke of the very large amount of sickness absenteeism "which arises not from what in the past we regarded as illness or disease but from those once vague and rather despised causes which passed under names such as neurasthenia," and which the chairman, Lord Horder, had described as stress diseases.

At the present time, said Sir Stafford, the country probably loses 40 million working weeks a year from sickness absenteeism; the average man loses 10 days a year, and the average woman 15 days, from sickness—or 3% and 5% of their working time. Nothing is more wasteful than the casual absence through sickness which often disrupts the flow of production.

> "A great deal of most useful work has of course been done on this subject, but we should all agree that the field is not yet by any means fully explored, and a great deal still remains to be done . . . . Both the Industrial Health Research Board and the Medical Research Council have done much excellent research, but it has not earned the practical appreciation and application which it deserves. If all the findings of those bodies were being applied in practice, we should certainly very much cut down this present degree of stress disease, with great benefits to all of us."

The close relation between stress sickness and industrial morale has been made clear, and it has been shown that the rate of absenteeism arising from this cause is at a minimum where

(1) the selection of employees is made on a proper and sound basis;

(ii) there are adequate chances of promotion for efficient workers;

(iii) there is full knowledge of the purpose and objects of the work; and

(iv) there is stability in the organisation itself.

A good deal of stress disease is being created by management through lack of understanding or failure to take the necessary preventive measures, and that emphasises the need for management and medical science to get together in the attack on this industrial handicap. In the Army during the war much was discovered about misfits and the stresses and strains of putting people into jobs which were either too much for them or too humdrum to engage their interest, and much too was done on selection; but the results of all this work have not received the study they merit in their application to manpower problems in industry.

> "During the war I got set up a committee of psychiatrists and psychologists to study these methods, with a view to their impact upon our post-war industrial problems. The publication of their report last year gave others an opportunity to study their work and the work that had been done in the Army, Navy, and Air Force, and I hope that study will not be neglected, as I am sure there is much to be learnt from it. To some extent we are trying to carry on that work through the panel that has been set up under Sir George Schuster's chairmanship, which is concerned with all the problems of industrial morale. I am delighted that Roffey Park through the person of Dr. Ling is contributing to that study."

The Goodenough Committee emphasised the need to include the problems of industrial health in student and postgraduate courses for medical men, and the Nuffield Foundation has given a lead in establishing university chairs of social and psychological medicine. The present Government increased the money allotted to the University Grants Committee to £12 million a year, much of which will go to medical education.

> "It is up to the medical schools to see to it that the social and industrial problems are given their rightful place in the educational syllabus. In the same way, I hope that the Departments of Commerce and similar faculties will devote some of their curriculum to the questions of human relations in industry. In this way we shall get the problem attacked from both sides simultaneously, which is what we need for success."

It is sometimes forgotten that today some 400,000 persons in this country are engaged in managerial functions of one kind or another, and that there are 12,000 entrants a year, many of whom at present are very ill equipped to appreciate the importance of the psychological factors in human relationships. All this is now recognised as a matter of first-class importance and is no longer regarded as the hobby of a few cranks. But in the average place of employment the practice lags very far behind the theory, and everything possible must be done to bring about the practical application of the remedies and methods that can now be safely advocated as cures or preventions of stress diseases. In the training department at Roffey Park, said Sir Stafford, regular courses are being provided for both doctors and industrialists, and the two partners are being brought into useful contact with one another.

In his introductory speech Lord Horder referred to the growing support for Roffey Park. This centre had treated and resettled 3600 men and women, of whom 80% were known to be working contentedly six months or more after leaving. The breakdowns which brought these people to Roffey arose from a number of causes—"the square peg in the round hole, poor factory conditions, bad morale, poorly trained departmental managers and foremen who spread an atmosphere of suspicion and unhappiness, and, of course, disharmonies in family life." At least 70% of all sickness absence in office and factory was accounted for by the "stress diseases." Prevention lay in training doctors and laymen alike in the fundamentals of healthy mental and physical living in an industrial environment. The impending amalgamation of Roffey Park with St. Thomas's Hospital, under the National Health Service Act, augured well for both institutions.

In England Now

A Running Commentary by Peripatetic Correspondents

CLAIMING priority is a dangerous game—hence this preliminary communication as a feeler before I put in a claim for my "Skymaster œdema."

Skymasters, as every schoolboy knows, are the four-engined Douglas planes which South African Airways use for their express air service between Johannesburg and London. The plane leaves Johannesburg shortly after midnight. The first stop is at Kisumu, at the northern tip of Lake Victoria, where passengers are taken to a hotel for lunch. The next stop is the same evening at Khartoum for dinner. Then, flying all night again, this time over the Sahara, there is a stop just before dawn at Castel Benito, the airport for Tripoli, and the next hop brings one to Heath Row, where the plane is scheduled to land shortly after midday. So the whole trip of some 6000 miles takes just over thirty hours. When full, the plane carries over forty passengers. No sleeping bunks are provided, and though the seats can be tipped back it is practically impossible to do so to any extent when the plane is full because either the back of your seat smothers the passenger behind you or your feet stick into the back of the passenger in front of you. The most that one can hope for during the two nights in the plane is to sit in a semi-recumbent position.

My attention was first drawn to the "new" disease by a senior colonial medical officer who had flown out to Johannesburg in this plane. Being of the old pioneering school who believe in being as comfortable as possible under all circumstances, he took his shoes off before settling down for the night. On waking in the morning he discovered that his ankles were so swollen that it was extremely difficult to get his shoes on. Visions of unsuspected cardiac or renal disease rose before him, but as a good Irishman he refused to be perturbed, and within twenty-four hours the œdema had gone and did not recur. A few weeks later a distinguished South African physician told me he had been consulted by a middle-aged lady with the same story.

When I flew home by Skymaster I was therefore well primed, and on settling down for my first night in the air I kept my shoes on. I examined my ankles at breakfast-time and there was nothing to swear to, so I began to think that my two "cases" must have what our American friends call "some underlying pathology." After my second night in the plane, however, both feet and ankles had the loveliest pitting œdema I have ever seen. And I can now sympathise with my patients when they complain of aching in their œdematous feet. It took about forty-eight hours for the pitting to disappear, and during this period my feet ached steadily whenever I walked about. That I was not the only victim was evident when I quietly studied the lower extremities of the other passengers; several of them had definite swelling.

The obvious comparison is with the "shelter legs" of the war. But this mainly affected elderly people, whereas I am nearer forty than fifty and my first informant was only just on the wrong side of fifty. Then again, shelter leg was supposed to be due to sitting still all night in a cramped position on a deck-chair, with the cross-bar obstructing the venous return. I admit that the conditions in the Skymaster (*pace* S.A.A.) could be described as cramped, but there was no hard bar at the front of our well-padded seats, and certainly in my case there was no question of keeping still all the time—on the contrary, one was continually turning from side to side, crossing and uncrossing one's legs and stretching them, trying to find a comfortable position. Perhaps I should add that the Skymaster has no pressurised cabin, and that at no time did we fly above 5000–7000 feet.

This may well be a recognised condition,* but I have yet to meet someone who knows about it. This brief note will have served its purpose if it allays the anxieties of passengers who awake to find their ankles œdematous.

---

* Alas for priority! A leading article on shelter legs in 1940 (ii, 722) mentioned that a similar condition had been seen in people flying home from Cape Town.—ED. L.

(2) That every coroner should keep adequate records, of which copies should be obtainable by interested persons on payment of a fee.

(3) That a consultative committee be set up to consider matters affecting the duties of coroners.

(4) That all inquests be in public; that in the case of an inquest on a "suicide" the press be prohibited from publishing an account of the proceedings and permitted only to publish the fact that an inquest has been held, the name and address of the deceased, and a verdict that the deceased died by his own hand.

(5) That early action should be taken to provide a full post-mortem service on a nation-wide scale.

A further recommendation—that as an interim measure urgent consideration should be given to mobilising pathologists and enabling them to travel to the various outlying mortuaries with fully equipped motorised laboratories—was withdrawn and referred to council after several representatives had objected that this proposal was unreasonable.

ELECTIONS

Dr. E. A. Gregg was elected chairman and Dr. J. A. Brown vice-chairman of the representative body. Mr. A. M. A. Moore was elected treasurer in succession to Dr. J. W. Bone. At the annual general meeting Sir Hugh Lett, the retiring president, inducted as president Sir Lionel Whitby.

Special Articles

HOSPITAL ADMISSIONS IN METROPOLITAN REGIONS

THE Metropolitan regional hospital boards have circulated a letter to local authorities and executive councils giving details concerning the admission of patients to hospitals in their area. As was explained in our leading article of June 19 (p. 951), the boards intend that as far as possible admissions shall be arranged direct between the doctor and the hospital. Where a doctor cannot secure a patient's admission to the hospital of his choice he should apply to the Emergency Bed Service (E.B.S.) who will try to find a suitable vacancy and if successful will arrange for the patient's transport to hospital. If free treatment is desired in any hospital not administered under the National Health Service, application must be made through the regional hospital board. A doctor representing the boards will be attached to the E.B.S.

Arrangements are being made to provide local admission centres, where necessary, throughout the regions. The establishment of these centres will take time and it will not be possible to complete arrangements for all areas by July 5. The E.B.S. has appointed officers to organise the admission system throughout the four metropolitan regions and these officers will visit all hospitals as soon as possible. Information concerning these centres will be issued locally.

Acute Sick.—Present procedure will be generally unchanged. Doctors may apply for admission direct to the hospital of their choice or through the E.B.S.

Non-urgent Cases.—Hospitals will maintain waiting-lists for non-urgent cases as at present, and will notify patients direct when a bed is available.

Chronic Sick.—There are now a large number of unstaffed beds for patients in this category and it is unlikely that additional nurses for these beds will be forthcoming for a considerable time. It will be necessary, therefore, for rigid selection to be exercised as regards admissions. Where the case is one of medical urgency the practitioner will apply to the nearest general hospital, and, if no bed is available, will apply to the E.B.S. for a vacancy. If the predominant need for admission is on social grounds, the E.B.S. will make arrangements through the appropriate medical officer of health for the home conditions to be investigated. If the case is not urgent the patient's name will be placed on the waiting-list of the nearest suitable hospital.

Infectious Diseases.—The present admissions procedure in the County of London area will be undertaken by the E.B.S., to which applications for admission should therefore be made. Uncomplicated cases of measles, chicken-pox, scarlet fever, german measles, or mumps will not be admitted to infectious disease hospitals unless the medical officer of health of the area supports the applications for admission, so in such cases applications should be made through the medical officer of health. Outside the County of London, doctors should apply direct to their nearest fever hospital or, if they cannot obtain a bed in this way, they should apply to the E.B.S.

Maternity.—Maternity patients will normally be admitted either on medical or social grounds. In the case of the former admission will be arranged between the practitioner and the hospital concerned; in the latter, a statement on social conditions will be required from the local health authority. In cases of obstetrical emergency application can be made to the E.B.S.

Mental Cases.—Mental cases requiring urgent admission will be dealt with by the duly authorised officer (who replaces the relieving officer), particulars of whom can be obtained from the local health authority. These officers will arrange for the admission of patients to mental observation wards or mental hospitals. Arrangements for the admission of voluntary patients under the Mental Treatment Act should be made direct with the appropriate mental hospital.

Mental Deficiency Act Cases.—Local health authorities remain responsible for the initial action; they should continue to arrange admissions direct with those mental-deficiency institutions within the National Health Service which they now use. If free treatment in a mental-deficiency institution outside the National Health Service is desired, application must be made to the regional hospital board and not to the institution.

Tuberculosis.—The E.B.S. will not be concerned with tuberculous cases save to arrange admission of emergencies—e.g., hæmoptysis—to a general hospital if required to do so. All recommendations for admission of tuberculous patients will normally come to the regional hospital board through the tuberculosis officers. Practitioners will refer all cases to the tuberculosis officer, who will make the appropriate recommendation for sanatorium or other treatment. No application for sanatorium treatment should be made to the E.B.S.

Convalescence.—Inquiries concerning convalescent beds may be made to the E.B.S. Further details will be issued to hospitals shortly.

The London offices of the Emergency Bed Service are at 10, Old Jewry, E.C.2, and the telephone number is Monarch 3000.

THE STRESS DISEASES

SIR STAFFORD CRIPPS AT ROFFEY PARK

OPENING the new training and research department at Roffey Park Rehabilitation Centre, Sussex, on June 12, Sir STAFFORD CRIPPS, Chancellor of the Exchequer, spoke of the very large amount of sickness absenteeism "which arises not from what in the past we regarded as illness or disease but from those once vague and rather despised causes which passed under names such as neurasthenia," and which the chairman, Lord Horder, had described as stress diseases.

At the present time, said Sir Stafford, the country probably loses 40 million working weeks a year from sickness absenteeism; the average man loses 10 days a year, and the average woman 15 days, from sickness—or 3% and 5% of their working time. Nothing is more wasteful than the casual absence through sickness which often disrupts the flow of production.

> "A great deal of most useful work has of course been done on this subject, but we should all agree that the field is not yet by any means fully explored, and a great deal still remains to be done . . . . Both the Industrial Health Research Board and the Medical Research Council have done much excellent research, but it has not earned the practical appreciation and application which it deserves. If all the findings of those bodies were being applied in practice, we should certainly very much cut down this present degree of stress disease, with great benefits to all of us."

The close relation between stress sickness and industrial morale has been made clear, and it has been shown that the rate of absenteeism arising from this cause is at a minimum where

(1) the selection of employees is made on a proper and sound basis;

without any publicity being given to them and without any complaint being made on that account.

Fellows of the college are quite at liberty to express and publish any views they may hold, but those attending a meeting at the college are not entitled to speak for the college as a whole. The council is charged with that duty, and also with taking such action on the views expressed at meetings as they may think fit. Pronouncements by the president have been made with the approval of the council, the body which has full responsibility and can be regarded as representative of the fellows as a whole.

The Royal College of Surgeons is an academic body and was founded, and granted powers and privileges, "to promote and encourage the study and practice of surgery." It fulfils these functions by maintaining high standards of examination for its diplomas, and by using its unique facilities for research and postgraduate education to the fullest possible extent. These are the true functions of the college, and its constitution is designed for their fulfilment. I quite agree that the college is not so constituted as to be an adequate body for day to day medicopolitical negotiations, and the council has repeatedly expressed this view.

Finally, I hope that the signatories of the letter in your columns will cease trying to use the college as a public platform for political purposes, and will join with the council and the majority of fellows in supporting the college, interesting themselves in its activities, and doing their best to carry it forward to an even greater position in the world of surgery than it has occupied in the past.

WEBB-JOHNSON
Royal College of Surgeons of England.   President.

THE GEOGRAPHICAL ORIGIN OF NURSES

SIR,—Though greatly impressed by Dr. Woolf's thorough and interesting study of this subject in your issue of June 19, I cannot help feeling that his conclusions lose some of their potential validity because of the method of geographical subdivision which he employed. To lump the county of London and the county boroughs together as "town" and to call the rest of England "country" shows some lack of appreciation of the typical English social pattern.

The population of the county of London is roughly 4,000,000. The population of the Metropolitan police district is about 8,000,000. Even when adjustments are made for the three considerable county boroughs in Greater London, a population not greatly less than that of the county of London lives in extrametropolitan London and has more in common with Dr. Woolf's "big-town" class than with his "rural" class. In all the other principal population centres of the country there is a pattern of city or great-town centre, with a small-town and suburban fringe separating it from the countryside and regarding itself as town rather than country; and in most cases the "fringe" population is not greatly less than that of the central city. Certainly, the majority of Dr. Woolf's "country" girls are not country-dwellers in any sense except the special and arbitrary one in which he uses the term.

The dullness of rural life probably plays some part in driving country girls into nursing, but two other important factors are seen to operate when one appreciates the true nature of the difference between the population groups concerned. "Fringe" areas usually contain a greater proportion of middle-class people than do "great-town" areas. In addition, great-town areas are more highly industrialised than fringe areas.

Hospitals tend to regard the middle-class girl as a better potential nurse than the working-class girl, because of her "better" educational and social background. Those fortunate hospitals which can still pick and choose their recruits, because of the glamour associated with their reputations and histories, deliberately pick the middle-class girls. In this way the great London hospitals and some of the major provincial hospitals close the door to town girls from their own areas. Again, it is anything but easy for a girl to live on the salary a probationer receives, even under the Rushcliffe scales. So long as the nurse's pay is kept low because of her "student" status, we can expect most recruits to come from the social group which can afford to subsidise its children's living up to the age of 21.

In the industrial areas the hospital is competing with the factory for its recruits, and the hospital is doomed to failure from the start. The factory offers more money and more freedom, and will accept its recruits at the age of 15. Other things being equal, the hospital might have an equal chance with the factory if both were willing to take the girl who had just left school; but nursing will find it hard to attract the girl who, at the age of 18, has already spent two years in another job.

It certainly behoves the hospitals to do what Dr. Woolf suggests: this will help them in any form of competition. But the problem is not merely one of recruiting the town girl: it is one of recruiting the working-class girl, to whom and to whose family economic considerations loom large. And in spite of the Working Party's cavalier dismissal of the "gap" between school-leaving age and entry upon nursing training, the possibilities opened up by prenursing training courses, especially when these are combined with maintenance allowances or with paid practical work in association with local authority or other medical services, are worthy of a good deal of study.

JOHN D. KERSHAW
Colchester.   Medical Officer of Health.

REGIONAL ILEITIS

SIR,—Perhaps I may make a few remarks on your interesting leading article of May 29. These are based on 12 cases seen in private practice between 1939 and 1947, and on others seen by me in the Army during the war, or in consultation. Some of them had been diagnosed as ulcerative colitis on account of chronic diarrhœa, and the true diagnosis was established only by investigation. A further indication for investigation was complications, among which the following were noted: retarded growth and development (intestinal dwarfism in one case), when the disease arose in childhood: mental abnormality, such as retarded intelligence or anxiety state; hyperchromic or hypochromic anæmia: iritis or iridocyclitis; and, once, non-union of a fracture.

The X-ray findings may clinch the diagnosis, but there is often supporting evidence—intermittent pyrexia, diarrhœa, leucocytosis, increased blood-sedimentation rate, intermittent occult blood in the stools, and increased fæcal fats.

The radiological examination (barium meal and barium enema) practically always shows a positive string sign of Kantor. At the same time, other abnormalities can be noticed: calcifying lymphadenitis in the right lower abdomen, and a cæcum irregular in outline and placed higher than normal. Radiology alone can reveal the extent of the disease, which may start practically in the stomach, affect intermittent parts of the jejunum and ileum, and be manifest also in the colon as segmental or polysegmental colitis.

The methods described here have been employed in all cases of chronic ulcerative colitis, a great number of which proved to be amœbic in origin; treated as such, they were greatly improved or cured. In almost all these cases the stools contained *E. histolytica*. In some the possibility of an amœbic infection was evident only after routine radiological examination of the chest, which showed an abnormally raised and irregular right diaphragm. The cases which were not proved to be amœbic could be divided into segmental colitis (Crohn) and idiopathic ulcerative colitis. In the group of segmental colitis, typical string signs were found in the terminal ileum, in addition to the abnormality in the colon; whereas in idiopathic ulcerative colitis no abnormality of the ileum was found; and the investigations did not show any signs of tuberculosis, diverticulitis, or other disease.

It is often suggested that chronic ulcerative colitis is the expression of an anxiety state or of some psychosomatic disorder. In my cases the disease persisted, though the general condition benefited by psychological treatment. Such a case was seen in July, 1947, and reinvestigated recently. Although the patient's general condition was greatly improved—her weight had risen from 9 st. 3 lb. to 10 st. 3 lb.—the radiological appearance of the colon had certainly not improved.

I don't know whether it's worth reading the medical journals each week (except of course for this column). My brain gets very battered having new facts put in so often and then having them extracted again. I was thinking last night of the number of things I have read which I later find refuted in another article, sometimes within a few months: just when I'd mugged up about fibrinoid necrosis of glomeruli causing vicious circle hypertension, I read elsewhere that all rats have got fibrinoid necrosis anyway and that the other work might be invalid. Just when I had it clear that crush syndrome kidneys got cortical necrosis from a nervous mechanism making the medullary bypass open out and the cortical vessels close down, somebody says that the cortical vessels are squashed by swollen cells and it isn't a nervous mechanism at all. Again, what about breast-milk? I've read in the last year that thyroid increased it, then that iodine alone was better still, and just lately that iodine doesn't increase it after all.

I really don't know what to believe or which side to take. If one keeps on packing and unpacking a suitcase with different contents everything gets muddled, containers burst, and toothpowder and hair-lotion impregnate the shirts and socks. That's what's going to happen to our brains if we go on poking in facts and plucking them out at the same time.

Some beliefs are cherished a long time before some pundit kills them for us, and the extraction of a firm-rooted belief is as unpleasant as the removal of an impacted wisdom tooth. I was brought up to believe that pulmonary œdema was due to left ventricular failure, but apparently it isn't today. As a student I fondly believed digitalis worked by shielding the ventricles from the futile rampagings of the auricles above them, but the Hammersmith chaps say I must cross it all out now and talk about right auricular pressure. We used to be taught that the rock dust and not the coal dust hurt the miners' lungs, but I see that the coal dust is the villain after all. Spina bifida has nothing whatever to do with enuresis, though it had when I was a boy. Though I'm anything but clever, as Captain Corcoran remarked, I could talk like this for ever.

What's to be done? I'm getting suspicious and distrustful of all medical literature, and I've a jolly good mind to cancel my subscription to THE LANCET and become a stockbroker. Stocks and shares are no more variable than medical theory, and one can make money out of *their* fluctuations.

* * *

A close study of the student nurse's education, in theory and practice, should be compulsory for any member of the medical profession concerned with its reorganisation. The only way to know what is going on is to hear from the student nurses themselves how and what they are taught. I have been following with interest the progress of a girl who entered the P.T.S. a few weeks ago.

Having "done" the skeleton in a week or two, with a distant view of the various bones during lectures and a closer view obtained in competition with fifteen other people, she was required in a test paper to draw a diagram of the skull. Joints were disposed of in an hour, in a practice-lecture by a sister-tutor in training. Now the muscular system has been dealt with, though no student has yet seen a muscle and the names are a curious conglomeration of old and new terminology. Somehow, the authors and illustrators of nursing textbooks never agree, so that the inguinal ligament of the text becomes the Poupart's ligament in a diagram, to add to the nurse's confusion.

In practical nursing they have all seen a dummy carefully washed with real soap, although the student nurse receives but one soap coupon a month. This dummy is invaluable, but when it came to a practical demonstration of enema technique the *two* holes (intake and output) provided (what will the nurse make of this anatomical arrangement?) were not used, and the enema was given into a basin.

* * *

A rural health visitor, having vividly described the dangers of raw milk to her little audience, asked whether in future they would order only pasteurised milk. "Nay," answered one thoughtful mother, "ah doan't think ah shall; ah'd rayther drink a menagerie than a cemetery."

Letters to the Editor

THE ROYAL COLLEGE OF SURGEONS

SIR,—I regret that the fellows of the Royal College of Surgeons of England who signed the letter in your issue of June 19 (p. 963) feel that they have a grievance about the conduct of meetings which have been held in the college in recent years. They were conducted strictly in accordance with the by-laws and regulations of the college. For the information of the general body of fellows it will be well for the facts to be put on record.

The meeting held on April 28 of this year was summoned with the approval of the council in response to a requisition signed by thirty-three fellows. It was, as stated by your correspondents, the first meeting of fellows since the National Health Service Act became law at which resolutions were in order.

There had, however, been the annual meeting of fellows and members in November, 1947, when questions relating to the Act could have been the subject of resolutions; but no notices of motion were received and there was no quorum at the meeting.

There had also been the meeting of fellows on Nov. 29, 1946, referred to by your correspondents. The council agreed to this meeting being summoned before Nov. 30 "for the exchange of views," in response to an urgent request at the annual meeting of fellows and members on Nov. 13, 1946, at which again there was no quorum. It was made clear that resolutions would not be in order since the statutory notice could not be given. The general opinion of the meeting was however expressed in a recommendation that the college should act in conformity with the general feelings of the profession in regard to the question of negotiating on the regulations of the Act. The council held the view that negotiations should take place, but, when the majority of the profession favoured the opposite course, they acted as requested.

Three resolutions were passed at the meeting on April 28 this year. They were as usual submitted to the council for consideration and such action as they might think desirable. The first resolution, which was passed *nem. con.*, urged the council that opinions expressed at the meeting be represented to the Minister of Health. This was done. The terms of the other two resolutions, which were passed by 153 to 73 and 67 to 58, were taken as representing the views of the meeting. The council were opposed to the resolutions but in accordance with usual practice members of the council did not vote. The resolutions were sent not only to the Minister (who personally acknowledged them) but also to the Negotiating Committee, through which body the council has acted in representing views to the Government. It can hardly be maintained, therefore, that opinion has been suppressed.

Meetings at the college are not public meetings; and representatives of the press, either lay or medical, are not invited as a rule, though the annual meeting of fellows and members is sometimes attended by representatives of the medical press. College meetings are held for the receipt of council reports and to enable those present to put their views before the council. Resolutions which are passed are reported to the council, which is responsible for the government and management of the college, and is representative of the fellows as a whole, not only those who happen to attend any particular meeting.

It is usual for proceedings at collegiate meetings to be confidential. Occasionally a college may issue resolutions for publication, but the proceedings of meetings are not usually open to the medical or lay press. The by-laws and regulations of the Royal College of Surgeons are strictly drawn in regard to the management of meetings, with a view to preventing them from being used as a means of publicity or an opportunity for propaganda.

During the discussions on the National Health Service Bill before enactment, many resolutions were passed at meetings of fellows, and of fellows and members. These were dealt with in exactly the same way as the later ones, and were sent by the council to the Negotiating Committee, and sometimes to the Minister of Health,

TWO QUALITIES OF SERVICE?

SIR,—You are to be congratulated on your annotation ast week. Surely the real difference in the future between a private and a State patient will be that the former will have an appointment to see his doctor at a time convenient to both, whereas the latter will attend at the doctor's regular consulting hours and take his turn with others.

Worthing. **HAROLD LEESON.**

ARTIFICIAL LIMBS

SIR,—Recent articles and letters in the press have referred to the artificial limbs to be provided in the new service as "standard" or "utility" limbs. As one of the firms of artificial-limb makers appointed to supply these limbs we have no knowledge whatsoever of a "standard" or "utility" limb. The limbless sent to us to be fitted with artificial legs each constitutes an individual case, and there is no such thing in our experience as standardisation. The appliances for children and adults born with congenital deformities are also individual in design for each case. Because of the size of our organisation we can employ specialist fitters for each site of amputation (incidentally we have no knowledge of a "standard amputation" but only of a good or bad stump for fitting) and we are probably the only firm in the world doing this.

To allay other fears which have been expressed we should like to make it clear that we have for years past carried out repairs to artificial legs of all makes, and we are in a position to continue to do so.

J. E. Hanger & Co. Ltd.
Roehampton.

A. W. SHAW
Managing Director.

HEALTH CENTRES

SIR,—One aspect of the proposed and now, alas, postponed introduction of health centres has not, I feel, been sufficiently stressed. This concerns the relationship between general practitioners and consultants. I believe that the extra facilities, such as radiological departments and laboratories, made possible by establishing health centres, would bring about a more normal and healthy relationship.

Fifty years ago, before the technical side of medicine became so advanced, a practitioner would seek the advice as consultant of a man whose clinical acumen was respected or who had had special experience in a particular type of disorder. The consultant would approach the case with the same implements for examination as the practitioner—i.e., his eyes, ears, sense of touch, and so forth. Nowadays, however, the practitioner starts at a technical disadvantage, since he is not in a position to use many of the methods of investigation in which he has been trained, and which would be useful to him. Hence the hospital specialist or consultant is now in some respects valued more because he has resources for these methods than because of his clinical acumen or experience. His work is greatly increased because many cases are sent not so much for advice as for that extra investigation. The diagnosis of pernicious anæmia, though it can be made very nearly by a laboratory technician, can seldom be made with any certainty by the general practitioner.

A properly organised system of health centres with direct access for the practitioner to laboratories and radiography facilities would improve the efficiency of the medical services in several ways:

1. It would reduce the amount of outpatient work at hospitals.

2. It would allow the general practitioner to use the methods of examination and investigation by which he has been trained to diagnose disease, and so greatly increase the quality and interest of his work.

3. It would counteract the tendency in the occasional less conscientious practitioner to become merely the tenant of an office for dispatching patients to hospital.

4. It would put the consultant and the general practitioner back into a proper relationship with one another, in that, on the whole, they would approach a case on the same terms. The consultant would not need to be called in for help in diagnosis solely because the practitioner was unable to do the investigation, but only because he was not certain of his interpretation of the findings.

It may be said that general practitioners would not have enough experience to prevent them overlooking disease or making mistakes through misinterpretation. I have even heard a case quoted, as an argument against such facilities in health centres, in which a healthy kidney was removed because the practitioner had mistaken a staghorn calculus on one side for a normal pyelogram. Without adequate safeguards such misinterpretations could possibly take place, but with visiting radiologists and pathologists to check X-ray and laboratory findings they should be rare.

A final word must be said on the differences of opinion about the scope and structure of "health centres"[1]—differences fostered by this rather vague name for them which could be abandoned with advantage. Some think of the centre as similar to the Peckham Health Centre, which concentrates on frequent overhauls of the healthy population. Others think of it as an outpost of a hospital in hitherto unserved country, and run by specialists and consultants as a kind of branch outpatient department. Much can be said in favour of both these ideas; but the first cannot be widely applied for many years, while the purpose of the second would be better served by having more hospitals with outpatient departments.

What is required, whatever its name, is a centre where practitioners can work under good conditions, with administrative staff to look after records and notes, and where they have direct access to those pathological and radiological services, without which they literally cannot nowadays make a diagnosis.

ATTACK ON RHEUMATISM

SIR,—In his letter of June 19 Dr. Stone is attacking the word "rheumatism," not the group of diseases. This word has the advantages of antiquity and of being customarily accepted. Any substitute must prove its worth.

The *Shorter Oxford English Dictionary* defines rheumatism as "a disease of which inflammation and pain of the joints are prominent features." The *Encyclopædia Britannica* states that rheumatism is a "general term for various forms of disease subdivided as follows: acute, subacute, chronic, muscular, and arthritic." It is clear that "rheumatism" refers to a group of diseases affecting a section of the body—the muscles, joints, and allied structures. "Rheumatology" therefore is the special aspect of medical science that cares for this group of diseases. The definition, admittedly loose, is anatomical. The neurologist deals with diseases of the central nervous system—an anatomical division—but no-one complains because tabes and disseminated sclerosis are not clinical varieties of the same disease.

The causation of many of the rheumatic diseases is unknown, but that is no reason to object to the term. If it were, then other branches of medicine would be in need of similar treatment. Altering the name of this group of diseases will not bring divine inspiration and solve our problems.

The example quoted by Dr. Stone is comparable to such a phrase as: "This man has palpitations; are they neurotic?" Misuse of words by others is no reason for changing them. No-one suggests that neurologists should be styled "nervous physicians," or that there should be such terms as "geriatric physician" or "venereal surgeon." I can see no reason why the term "orthopædic physician" should be introduced, if only because I should not like to see broken bones in the rheumatic clinic.

London, S.W.1. **DAVID P. NICHOLSON.**

St. Thomas's Hospital have once more published their list of old students. This first post-war edition also contains the school's roll of honour and the names of those who have died since 1938. The kindly pre-war custom of free distribution has had to be reluctantly abandoned, but copies may be had from the beadle of the medical school for 2*s.* 6*d.*

---

[1] *Lancet*, 1947, i, 32.

Lastly, I should like to mention the following case of a man who first came to me in May, 1947, with four weeks' history of abdominal pain and loss of weight (1 st.). During this period he had had two or three severe attacks of acute pain, each lasting about twelve hours.

While serving in the Army, this patient had repeated attacks of diarrhœa and abdominal pain. He was investigated on several occasions, with completely negative results. There had been a tendency to diarrhœa since 1941. He was discharged from the Army in 1945, diagnosed as an anxiety state. Clinical examination revealed a large mass in the centre of the abdomen which was movable, and could be felt at the right and left of the umbilicus. At times a well-marked increase of peristalsis in the left abdomen was noticed. A provisional diagnosis of subacute small-intestinal obstruction due to Crohn's disease was made. Operation on May 30, 1947 (Mr. E. W. Riches), showed subacute obstruction of the jejunum, caused by acute jejunitis (Crohn's disease) of mid-jejunum. In addition, four other areas of this disease were found. In the terminal ileum—the classical position—only the scar of previous inflammation could be seen; but other areas showed signs of healing, or were in a subacute non-obstructive stage. There was extensive lymphadenitis.

From my cases I did not derive the impression that this disease is more prevalent among Jews than others, only 6 out of a total of 24 patients being Jewish or of Jewish extraction.

POST-CRICOID PHARYNGO-ŒSOPHAGEAL PERFORATION

SIR,—"When the head is *extended*, as it *must* be during the introduction of the . . . œsophagoscope . . . ." (my italics). This sentence at the foot of p. 986 (Mr. Goligher's article of June 26) caught my attention, since for 20 years I have preached and practised, in some hundreds of cases, the exact opposite. I am aware that the view is current. But extension of the head, and still more extension of the neck which is hard to avoid if the head is extended, means that the instrument is brought up hard against the seventh cervical vertebra, and may even inflict damage in that region. It is usually possible to introduce an endoscope with the head extended, but it is always much easier and safer with the head and neck fully flexed forward. Let anyone try; it is clear at once that in flexion the instrument passes directly down the lumen of the œsophagus in the natural line of that lumen—the better the flexion, the easier the manœuvre. I commend this point particularly to the novice, especially when he is searching for a foreign body. Of course, once in the œsophagus gradual extension is needed for further progress; indeed, on my own operating-table (Thackray) there is an additional joint to provide mid-dorsal extension on approaching the cardia. But for the introduction of any instrument the rule, for ease and safety, should be "full flexion of neck and of head on neck."

BACTERIOLOGICAL NOMENCLATURE

SIR,—Unless workers in this country express their disapproval more strongly than they have done in the past, Bergey terminology is likely to become the international standard for bacteriological nomenclature. This country is adequately represented on the Nomenclature Committee of the International Association of Microbiologists, but on the more important Judicial Commission on Bacteriological Nomenclature we are represented by a mycologist. One of the permanent secretaries, Dr. R. St. John-Brooks, formerly acted as the mouthpiece of British bacteriologists, but since he now lives in the U.S.A. he is no longer in a position to represent opinion in this country.

It is important that some means should be found to keep our representative on the commission informed on the views of British bacteriologists, and an advisory nomenclature committee, preferably set up by one of the scientific societies, could do this. All British members of the International Nomenclature Committee would be on this committee and its other members would be bacteriologists representing medical, veterinary, agricultural, and industrial interests. The committee would have two main tasks: first, to define genera and species that should be afforded recognition; secondly, to review and prepare opinions on the problems to be considered by the International Judicial Commission at its next meeting. Many of these problems are highly controversial, and, unless our sole representative is adequately briefed, British bacteriological opinion is not likely to be heard by the commission.

CURARE IN ANÆSTHESIA

SIR,—As you pointed out in an annotation two years ago,[1] it was Bennett and Griffiths in Canada who revived the interest of clinicians in curare. But as early as 1912 Laewen, the German surgeon, was using curare for muscle relaxation in anæsthesia.[2]

Zwickau, Saxony. MAX DETLEFSEN.

SCHOOL DOCTORS AND THE ACT

SIR,—What is the position of school doctors under the Act? I have received a notice from my son's preparatory school telling me that the school doctor will accept the boys as patients under the Act, but in addition there will be a termly charge, which is to be paid to the doctor as an honorarium for his visiting the boys at school instead of insisting that they should go to his surgery. I felt that it was contrary to the spirit and the letter of the Act that the doctor should receive payment apart from the capitation fee for patients on his list. I rang up the Ministry of Health and they confirmed my view that the procedure was "highly irregular," but they admitted that the particular problem of *visits* of school doctors had not yet been considered.

I have since been told that the Preparatory Schools Association is recommending the payment of an honorarium to all school doctors, and I know of at least one public school at which the same thing is proposed.

FATHER OF EIGHT.

EARLY DIAGNOSIS OF GASTRO-INTESTINAL CANCER

SIR,—In the first decades of this century, at a time when great emphasis was laid on painstaking examination of the abdomen, two forms of gastric cancer were distinguished: one palpable and the other impalpable. In those days it was generally admitted that cancer of the stomach is nearly always inoperable, for by the time that the tumour has become palpable it has extended over a great part of the stomach and of the regional glands. Sometimes however—for example, with tumours involving the posterior wall of the stomach and invading the pancreas—the condition may become inoperable without the tumour ever being palpable.

It is deplorable that, as Mr. Hermon Taylor makes clear in his article of April 17 (p. 581), the position is still substantially the same. Moreover, tumours elsewhere in the digestive tract may also remain symptomless for a time, the appearance of symptoms being followed quickly by the state of inoperability. It thus seems desirable, as Mr. Taylor says, to adopt some method which will indicate the presence of a tumour of the alimentary tract in general, even if this method gives no evidence of the exact location. More than 30 years ago I pointed out, for the first time, the significance of finding occult blood in the fæces.[3] It was then shown that this finding is not characteristic of chronic peptic ulcer but is constant with cancers of the alimentary tract, irrespective of their site. Mr. Taylor proposes that each year 1 in 25 of the 45–60 age-group should undergo radiological examination. I suggest that each year every person in this age-group should have two examinations of the fæces for occult blood. The test is easy, cheap, and quick. If the patient is properly prepared, and if other conditions which may cause it to become positive—e.g., pyorrhœa, hæmorrhoids, and congestive heart-failure—can be ruled out, a positive result would call for a detailed X-ray study.

Sydney. EUGENE J. ROSENTHAL.

2. *Beitr. klin. Chir.* 1912, 80, 168.
3. Rosenthal, E. J. *Berl. klin. Wschr.* 1916, no. 35.

I am hoping that as we gain accumulative experience this practice will disappear. I am sure that it is believed in only by a very small minority of the medical profession, and I believe that as experience develops this alleged dichotomy in that service will be prevented. But, as I have said, such conduct is entirely unethical, and ought to receive the disapproval of the House and the country.

Mr. Wilson Harris: Is there any specific remedy when, as in a case which I know myself, a doctor refuses to take a patient on the grounds that the patient is in a position to pay, and therefore will not be accepted on the general list?—Mr. Bevan: If there are patients who are so informed they can, of course, go to another doctor. If at the end of the process there are patients who are without a doctor they may be assigned to one.

Mrs. Mabel Ridealgh: Is the Minister prepared to take action at a later date in cases where a doctor is prepared to take a husband and wife, but refuses to take the children unless the parents pay private fees for the children?—Mr. Bevan: There have been one or two instances of that kind. I believe that this action is also frowned upon by the medical profession and it only serves to show how necessary it is to organise this profession into a service for the nation as a whole in order to raise its standard of conduct.

Dr. S. Segal: Will not the Minister enlist the active coöperation of these patients in reporting such cases to the proper authority?—Mr. Bevan: They are obviously making their complaints known now, otherwise we would not have heard about them.

Patients Outside Doctor's Area

Mr. G. C. Touche asked the Minister if he was aware that some persons joining the National Health Service had been told that they could not retain the services of the doctor whom they had engaged for several years because they lived outside the area for which the doctor was zoned; and if he would amend the regulations to enable such persons to retain the services of their present medical advisers.—Mr. Bevan replied: A doctor has the right when joining the service to fix the area within which he will visit patients in their homes, as he is required to do when necessary. There is nothing to stop him accepting patients who live outside this area provided he is prepared to visit them.

Decentralisation of Local Health Services

Mr. G. H. Oliver asked the Minister, having regard to the decision of the Derbyshire county council not to delegate any of the duties under part III of the National Health Service Act to the borough of Ilkeston, how many county councils had disregarded his advice in adopting this course; and whether he would effectively intervene in cases where the health services were permitted to fall below the present standard of efficiency.—Mr. Bevan replied: Of 62 county councils in England and Wales, 27 have not decentralised the administration of their health services, but this figure includes some counties in which decentralisation would be inappropriate. I should certainly intervene wherever services of a proper standard were not being provided. Mr. Oliver: Could the Minister be induced to ask the county councils exercising their discretion not to delegate their powers under part III to state their reasons for their action to the smaller authorities whose health service they intend to supersede, particularly when the service is being run efficiently?—Mr. Bevan: The local authorities are acting within their powers and I have no statutory power to interfere. I can only intervene if the standards of the service are not high enough.

Maternity Medical Services

Mr. Somerville Hastings asked the Minister why he had decided to reverse the policy of Statutory Instrument 506 as regards the method of obtaining maternity medical services by encouraging doctors who had had no midwifery experience to undertake maternity work and arranging to pay them for it.—Mr. Bevan: I have decided after consultation with the medical profession to provide a lower fee for maternity medical services undertaken for his own patients by a doctor with ordinary experience. Such a doctor could not otherwise receive any fee for such services, either from public funds or from the patient. This does not affect the higher fees for special experience or the main objective that maternity work should generally be done by practitioners with such special experience. Mr. Hastings: Does this not mean that doctors who have seen no midwifery cases for 20 years or more will be able not only to undertake them but will be paid for them by the nation, and does he not think that this is a public danger and a scandal?—Mr. Bevan: This does not alter the existing situation. A general practitioner can do obstetrical work now and does it, so there is no new scandal being created. What is happening is that a new system is being introduced which will mitigate the present evils and I hope before long entirely remove them. Mr. Hastings: Does not the Minister feel that as he is responsible for the quality of the service he ought to take some steps to see that it is of a sufficient quality?—Mr. Bevan: Steps are being taken. The scheme is to create a panel of general practitioners who will do obstetrical work and relieve other general practitioners without the same experience from doing it. This will in fact powerfully modify and improve the existing practice.

Commander T. D. Galbraith: Can we really give official recognition to what is an undesirable practice?—Mr. Bevan: I cannot quite understand what the hon. Member means. What this means is that a doctor will be paid for obstetrical work if he does that work for his own patient at the request of his own patient. This is, in fact, an attempt to preserve the relationship for which hon. Members opposite have clamoured for two years.

Call-up of Medical Practitioners

Sir Ernest Graham-Little asked the Minister whether he was aware that the recent call-up of young medical practitioners, notwithstanding earlier representations that the supply was more than adequate, had caused hardship to those holding A appointments at the hospitals, who would thus be prevented from proceeding to B2 appointments, with detriment to their professional careers and, in particular, would make it impossible fully to carry out the recommendations of the Goodenough Committee, which declared that house-appointments for one year should be the minimum experience for the young practitioner before commencing practice; and if he would rectify this position.—Mr. Bevan replied: I am fully aware of the implications of the decision referred to. The Medical Priority Committee, on whose advice the decision was taken, recommended it as an exceptional means of meeting an expected deficiency in young practitioners for the Services during the second half of the year. The position will be reviewed towards the end of the year.

Supply of Artificial Limbs

Captain John Crowder asked the Minister of Pensions whether patients applying for artificial limbs under the National Health scheme after July 5 would be supplied with only one type of limb; and whether orders would be placed only with his department's sole contractors.

Sir John Mellor asked the Minister why, under the National Health Service, artificial limbs might be supplied by two firms only, to the exclusion of all other makers; and whether he would enable users to choose any make of limb preferred, provided additional expense does not fall upon public funds.

Mr. George Buchanan replied: This matter is under consideration. I hope shortly to be able to make a statement.

Captain Crowder: Is it the present position that a disabled man who wants his artificial limb repaired will have to pay for it himself unless he goes to one of the Government's sole contractors?—Mr. Buchanan: The present position is that the scheme is not started, so that at present a person other than an ex-Serviceman must pay for it unless he comes under a Ministry of Labour scheme. However, this matter is being considered, and I would like to leave it at that at the moment.

Sir John Mellor: Cannot the Minister give an assurance that users will be permitted to make their own choice provided no additional expense falls on public funds?—Mr. Buchanan: I hope people will be reasonable on this matter. I hope I am not an unreasonable Minister, and I hope that the people I am negotiating with in this matter will bear in mind the general interests of the community. If all of us are reasonable, I am sure we can work it out in a reasonable way.

Mr. Louis Tolley: Will the Minister make a statement at the earliest possible moment? I can assure him that many disabled men are showing real concern at the fact that in all probability in the future they will not be able to go to the makers for repairs and replacements, and they are disturbed as to what their future is likely to be.—Mr. Buchanan: In my view they need not be disturbed at all. I do not want any Party conflict on this, but nobody need be disturbed. The limb we make now is made for the persons who served in H.M. Forces during the war. That has been done for years without any reasonable complaint.

Public Health

Scarlet Fever in Lanarkshire

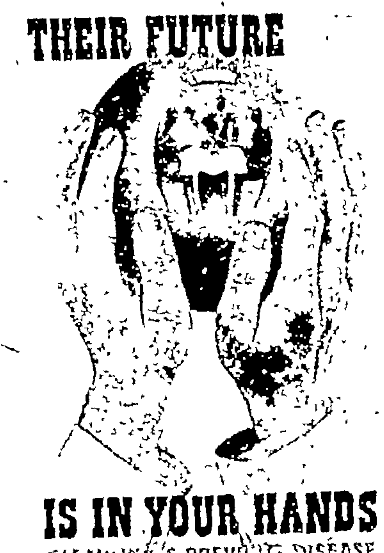
OVER 70 cases of scarlet fever were reported in the Lanark area between June 10 and June 17. All of these patients had eaten ice-cream from a shop in Lanark, where two assistants were found to be carriers of a hæmolytic streptococcus. The shop was closed for disinfection, and farms in the district were visited to make sure that workers handling milk were not carriers. The outbreak has now subsided.

Food-poisoning from "Cream" Buns

The medical officer of health for Lambeth has reported that on and after May 19 there were 93 cases of food-poisoning in this district, in all of which synthetic cream was incriminated. Each of the patients had eaten the cream in buns and cakes sold by the same confectioner on May 15. *S. typhi-murium* was isolated from a sample of cream taken on the 18th. At the bakery supplying the confectioner it was found that one of the staff had been absent from work with an illness suggesting food-poisoning; and *S. typhi-murium* was isolated from the fæces of another employee. The M.O.H.'s report points out that a local authority can legally forbid a carrier of enteric or dysentery to handle food for human consumption but that similar measures cannot be taken against a carrier of salmonella organisms. The M.O.H. urges that this discrepancy should be corrected.

Towards Cleanliness in Catering

A campaign launched by the British Tourist and Holidays Board, with Government support, has as its object the promotion of improved hygiene in the various sections of the catering industry. As the first step, attention is being drawn to the dangers of infected food and utensils and to the importance of personal cleanliness. Each of the 184,000 catering establishments in the United Kingdom has been sent posters and aluminium plaques for exhibition in staff quarters. One of the posters is reproduced here. Another, showing a dirty knife casting a shadow of a dagger, has this caption: "*Dangerous Weapons—Dirt Means Disease. Keep Foods, Hands, and Utensils. Clean.*" The theme of clean hands is continued on the plaques, which are designed to hang over wash-basins and in lavatories. Managements and staffs are to be invited to conferences at which the dangers of unclean habits in their work will be discussed.



Parliament

QUESTION TIME

Treatment under the National Health Service

Mr. H. E. RANDALL asked the Minister of Health how many instances of doctors informing their patients that there was a restriction on drugs which might be ordered for free supply for the proper treatment of patients under the new health service had been brought to his attention; what steps he had taken in the matter; and what action was open to patients so informed by their doctors.

Mrs. LEAH MANNING asked the Minister if he was aware that certain doctors were urging patients who go to them to be placed on their register to remain as private patients on the grounds that they would in that event receive better attention and be entitled to certain drugs which they could not have as National Health patients; and what steps he proposed to take to prevent such action.—Mr. ANEURIN BEVAN replied: I trust there have not been many such cases, and I am confident that doctors will not attempt to discriminate between those who use the service and those who do not. Moreover, I welcome this opportunity to make it clear that patients are entitled under the new health service without restriction to every kind of drug and appliance necessary for their treatment. Indeed, any doctor who failed to prescribe those drugs would be breaking his terms of service.

Mr. RANDALL: Is the Minister aware that two such cases have been brought to my attention? Will he give an assurance that he will make the fullest inquiry? Furthermore, will he answer the latter part of the question in which I ask what appropriate steps can the patients take when a doctor makes this statement?—Mr. BEVAN: The course open to the patient is to make a complaint to the local executive council and that body will investigate the complaint. There is machinery under the Act to deal with this matter.—Mrs. MANNING: In view of the fact that I have also sent two cases to the Minister, and as this is a matter which is causing great anxiety among people of all parties, and belonging to many classes, who have looked forward to being free from the burden of doctors' bills in the future, can he tell the House what steps he himself will take to end this rather disgraceful action on the part of some doctors?—Mr. BEVAN: All I can do is to answer the questions here, to call general attention to the facts, and to ask the public to note what is being said here, and not to listen to what certain doctors, who have been acting well below the ethical standards of the profession, have said.

Colonel M. STODDART-SCOTT: Will the Minister assure the House that doctors will not be surcharged for supplying certain drugs as they are at present under the panel system?—Mr. BEVAN: There are regulations concerned with the nature of the drugs to be prescribed. There are certain things prescribed as drugs which are not drugs, champagne, for example.

Dr. L. HADEN GUEST: Is the Minister aware that the British Medical Association take the strongest view of the improper conduct which a few doctors have been following, as suggested in these questions, and that they are taking action to bring this to the attention of the whole profession? Does not the Minister agree that, since the B.M.A. are now coöperating in order to give the best possible service under the slogan of Dr. Dain that "Only the best is good enough," it is desirable that their help in this matter should be welcomed by the Minister?—Mr. BEVAN: I have already welcomed the help that has been given by Dr. Dain, especially in a letter which he wrote recently to the *Times*. I am happy to think that the vast majority of the medical profession frown disapprovingly upon these practices.

Registration of Patients

Miss ALICE BACON asked the Minister under what authority a doctor refused to take a person on his list, and intimated that he was prepared to take the same person as a paying patient.—Mr. BEVAN replied: Such conduct is quite unethical and I confidently expect that the profession will express the strongest disapproval of it. Miss BACON: Is the Minister aware that this is happening, and that these practices give point to the criticism made by some supporters of the Government during the debate on the second reading of the National Health Service Bill, namely, that to allow a doctor in a public service also to undertake private practice is a means of destroying public confidence in the whole scheme?—Mr. BEVAN:

I am hoping that as we gain accumulative experience this practice will disappear. I am sure that it is believed in only by a very small minority of the medical profession, and I believe that as experience develops this alleged dichotomy in that service will be prevented. But, as I have said, such conduct is entirely unethical, and ought to receive the disapproval of the House and the country.

Mr. Wilson Harris: Is there any specific remedy when, as in a case which I know myself, a doctor refuses to take a patient on the grounds that the patient is in a position to pay, and therefore will not be accepted on the general list?—Mr. Bevan: If there are patients who are so informed they can, of course, go to another doctor. If at the end of the process there are patients who are without a doctor they may be assigned to one.

Mrs. Mabel Ridealgh: Is the Minister prepared to take action at a later date in cases where a doctor is prepared to take a husband and wife, but refuses to take the children unless the parents pay private fees for the children?—Mr. Bevan: There have been one or two instances of that kind. I believe that this action is also frowned upon by the medical profession and it only serves to show how necessary it is to organise this profession into a service for the nation as a whole in order to raise its standard of conduct.

Dr. S. Segal: Will not the Minister enlist the active coöperation of these patients in reporting such cases to the proper authority?—Mr. Bevan: They are obviously making their complaints known now, otherwise we would not have heard about them.

Patients Outside Doctor's Area

Mr. G. C. Touche asked the Minister if he was aware that some persons joining the National Health Service had been told that they could not retain the services of the doctor whom they had engaged for several years because they lived outside the area for which the doctor was zoned; and if he would amend the regulations to enable such persons to retain the services of their present medical advisers.—Mr. Bevan replied: A doctor has the right when joining the service to fix the area within which he will visit patients in their homes, as he is required to do when necessary. There is nothing to stop him accepting patients who live outside this area provided he is prepared to visit them.

Decentralisation of Local Health Services

Mr. G. H. Oliver asked the Minister, having regard to the decision of the Derbyshire county council not to delegate any of the duties under part III of the National Health Service Act to the borough of Ilkeston, how many county councils had disregarded his advice in adopting this course; and whether he would effectively intervene in cases where the health services were permitted to fall below the present standard of efficiency.—Mr. Bevan replied: Of 62 county councils in England and Wales, 27 have not decentralised the administration of their health services, but this figure includes some counties in which decentralisation would be inappropriate. I should certainly intervene wherever services of a proper standard were not being provided. Mr. Oliver: Could the Minister be induced to ask the county councils exercising their discretion not to delegate their powers under part III to state their reasons for their action to the smaller authorities whose health service they intend to supersede, particularly when the service is being run efficiently?—Mr. Bevan: The local authorities are acting within their powers and I have no statutory power to interfere. I can only intervene if the standards of the service are not high enough.

Maternity Medical Services

Mr. Somerville Hastings asked the Minister why he had decided to reverse the policy of Statutory Instrument 506 as regards the method of obtaining maternity medical services by encouraging doctors who had had no midwifery experience to undertake maternity work and arranging to pay them for it.—Mr. Bevan: I have decided after consultation with the medical profession to provide a lower fee for maternity medical services undertaken for his own patients by a doctor with ordinary experience. Such a doctor could not otherwise receive any fee for such services, either from public funds or from the patient. This does not affect the higher fees for special experience or the main objective that maternity work should generally be done by practitioners with such special experience. Mr. Hastings: Does this not mean that doctors who have seen no midwifery cases for 20 years or more will be able not only to undertake them but will be paid for them by the nation, and does he not think that this is a public danger and a scandal?—Mr. Bevan: This does not alter the existing situation. A general practitioner can do obstetrical work now and does it, so there is no new scandal being created. What is happening is that a new system is being introduced which will mitigate the present evils and I hope before long entirely remove them. Mr. Hastings: Does not the Minister feel that as he is responsible for the quality of the service he ought to take some steps to see that it is of a sufficient quality?—Mr. Bevan: Steps are being taken. The scheme is to create a panel of general practitioners who will do obstetrical work and relieve other general practitioners without the same experience from doing it. This will in fact powerfully modify and improve the existing practice.

Commander T. D. Galbraith: Can we really give official recognition to what is an undesirable practice?—Mr. Bevan: I cannot quite understand what the hon. Member means. What this means is that a doctor will be paid for obstetrical work if he does that work for his own patient at the request of his own patient. This is, in fact, an attempt to preserve the relationship for which hon. Members opposite have clamoured for two years.

Call-up of Medical Practitioners

Sir Ernest Graham-Little asked the Minister whether he was aware that the recent call-up of young medical practitioners, notwithstanding earlier representations that the supply was more than adequate, had caused hardship to those holding A appointments at the hospitals, who would thus be prevented from proceeding to B2 appointments, with detriment to their professional careers and, in particular, would make it impossible fully to carry out the recommendations of the Goodenough Committee, which declared that house-appointments for one year should be the minimum experience for the young practitioner before commencing practice; and if he would rectify this position.—Mr. Bevan replied: I am fully aware of the implications of the decision referred to. The Medical Priority Committee, on whose advice the decision was taken, recommended it as an exceptional means of meeting an expected deficiency in young practitioners for the Services during the second half of the year. The position will be reviewed towards the end of the year.

Supply of Artificial Limbs

Captain John Crowder asked the Minister of Pensions whether patients applying for artificial limbs under the National Health scheme after July 5 would be supplied with only one type of limb; and whether orders would be placed only with his department's sole contractors.

Sir John Mellor asked the Minister why, under the National Health Service, artificial limbs might be supplied by two firms only, to the exclusion of all other makers; and whether he would enable users to choose any make of limb preferred, provided additional expense does not fall upon public funds.

Mr. George Buchanan replied: This matter is under consideration. I hope shortly to be able to make a statement.

Captain Crowder: Is it the present position that a disabled man who wants his artificial limb repaired will have to pay for it himself unless he goes to one of the Government's sole contractors?—Mr. Buchanan: The present position is that the scheme is not started, so that at present a person other than an ex-Serviceman must pay for it unless he comes under a Ministry of Labour scheme. However, this matter is being considered, and I would like to leave it at that at the moment.

Sir John Mellor: Cannot the Minister give an assurance that users will be permitted to make their own choice provided no additional expense falls on public funds?—Mr. Buchanan: I hope people will be reasonable on this matter. I hope I am not an unreasonable Minister, and I hope that the people I am negotiating with in this matter will bear in mind the general interests of the community. If all of us are reasonable, I am sure we can work it out in a reasonable way.

Mr. Louis Tolley: Will the Minister make a statement at the earliest possible moment? I can assure him that many disabled men are showing real concern at the fact that in all probability in the future they will not be able to go to the makers for repairs and replacements, and they are disturbed as to what their future is likely to be.—Mr. Buchanan: In my view they need not be disturbed at all. I do not want any Party conflict on this, but nobody need be disturbed. The limb we make now is made for the persons who served in H.M. Forces during the war. That has been done for years without any reasonable complaint.

I take it that if those who have this limb are fairly satisfied, it is not a bad limb for other people as well.

Mr. L. D. Gammans asked the Minister why, under the new Health Act, only one firm has been selected to make artificial legs and one other firm to make artificial arms; why the remaining 25 limb-making firms are excluded; and to what extent artificial limbs are being made on semi-mass-production lines.—Mr. Buchanan: The matters referred to in the first part of the question are under review and I hope to make a statement shortly. As regards the last part of the question all artificial limbs supplied by the Ministry of Pensions are fitted to the needs of the individual although as in other productions some parts are made in quantity. Colonel Leonard Ropner: Can the Minister give an assurance that his policy is not to establish anything in the way of a monopoly in the making of artificial limbs? Is he aware that, rightly or wrongly, there is an impression amongst these unfortunate men and women that something is happening behind the scenes which will limit their choice of the manufacturer of the artificial limbs?—Mr. Buchanan: Having talked with the people concerned in this matter, I hope to make a reasonable adjustment. Mr. John Hynd: Will the Minister tell the House when this so-called monopoly was first established?—Mr. Buchanan: This so-called monopoly has been going on all the time. For a long time the main contractor has had the monopoly of supplying limbs to those who suffered as a result of the war.

Mr. Gammans: In view of the fact that the Minister is not able to give an assurance that a monopoly will not be set up in artificial limbs—[Hon. Members: "He said so"]—I beg to give notice that I shall raise this matter on the Adjournment.

Mr. H. D. Hughes asked the Minister whether non-pensionable limbless ex-Servicemen in employment are entitled to receive a duplicate issue of artificial limbs.—Mr. Buchanan: All ex-Servicemen who lost a limb during war service are provided with a duplicate artificial limb. Under the National Health Service duplicate artificial limbs will be provided on the same lines as to the war-disabled.

Tuberculosis Beds in Scotland

Mr. T. F. Hubbard asked the Secretary of State for Scotland the number of pulmonary tuberculosis cases in Scotland for whom hospital treatment was recommended but accommodation was not available?—Mr. Arthur Woodburn replied: There were 2378 cases of pulmonary tuberculosis on the local authorities' waiting-lists for admission to hospital on March 31.

Publications in the Colonial Medical Service

Sir Ernest Graham-Little asked the Secretary of State for the Colonies whether he was aware that his circular 12412/12.2.48, requiring that essays by medical officers in the Colonial Service which it was desired to publish should be first submitted to him to ensure that nothing was published which might misrepresent the policy of the Colonial governments, had caused misgiving amongst medical officers in the service; and if he would recall this instruction?—Mr. Creech Jones replied: No information has reached me that this circular has caused misgiving. The question implies that the effect of this circular was to impose a new general regulation about publications by medical officers in the Colonial Service. In fact, its purpose was to inform Colonial governments of a generous offer by the National Association for the Prevention of Tuberculosis to award a prize of 100 guineas for an essay on the control of tuberculosis in Colonial territories and the reference to the publication of essays was only incidental. One of the rules of the competition says that essays sent in shall become the property of the N.A.P.T. and that any of them may be published at its discretion in the author's name. The circular drew attention to this and said that in order to ensure that nothing is published which might misrepresent the policy of Colonial governments or of H.M. Government, the secretary-general of the association had agreed to arrange that essays which it is desired to publish should first be submitted to the Colonial Office. This conforms generally with Colonial regulation 57, one of whose provisions is that an officer shall not, without the express permission of the Secretary of State or of the governor, publish in any manner anything which may be reasonably regarded as of a political or administrative nature. I think it was right in the interests of all concerned to make this precautionary arrangement and I see no reason why it should be altered. There is no intention whatever of fettering free scientific discussion.

Appointments

Dolton, E. G., M.B. Lond., F.R.C.S.: asst. surgeon (thoracic), Royal Hospital, Wolverhampton.

Jackson, I. M., B.A., M.B. Camb., F.R.C.S., M.R.C.O.G.: surgeon to outpatients, Chelsea Hospital for Women.

Mackenzie, Ian, L.R.C.P.E.: second asst. M.O., The Mental Hospital, Isle of Man.

Parker, W. S., M.B. Manc., D.P.H., D.I.H.: asst. county M.O., Norfolk; M.O.H., Erpingham, Cromer, North Walsham, and Sheringham; and M.O., East Norfolk Joint Isolation Hospital, Roughton.

Parr, T. P., M.D. Edin., D.P.M.: asst. M.O., South-western Regional Hospital Board.

Quilliam, R. L., M.R.C.S., D.P.M., D.M.R.D.: radiologist, St. James Hospital (L.C.C.).

Shield, J. B., M.B. Edin., F.R.C.S.E.: asst. orthopædic surgeon, Royal South Hants and Southampton Hospital.

Townsend, C. Geoffrey, M.B. Camb., D.A.: anæsthetist, Seamen's Hospital, Greenwich.

South-West Metropolitan Regional Hospital Board:

Senior assistant M.O.:

Anderson, P. C., M.D. N.Z., F.R.C.S.E., M.R.C.P.
Revans, John, M.B.E., M.R.C.S., D.C.H.

County Borough of West Ham:

Florentin, Miriam, M.B. Manc., D.P.H.: senior asst. M.O., maternity and child welfare.

Wigley, G. S., M.R.C.S., D.P.H.: deputy M.O.H. and deputy school M.O.

Colonial Service:

Bennett, J. P., M.B. Durh.: travelling M.O., Sarawak.
Davies, J. G., M.B. Edin., D.T.M. & H.: M.O., Malaya.
Dean, N. M. B., M.B. Edin.: M.O., Nigeria.
Fung-Kee-Fung, C. O., M.B. Lond., F.R.C.S.: asst. surgeon, Public Hospital, Georgetown, British Guiana.
Herlinger, Hans, M.D. Malta: M.O., British Guiana.
Lester, H. M. O., O.B.E., PH.D., B.SC. Lond., M.R.C.S., D.T.M. & H.: director of tsetse and trypanosomiasis research and reclamation, East Africa.
O'Malley, O. M., M.B. Dubl.: M.O., Malaya.
O'Neill, P. L., F.R.C.S.E., D.L.O.: M.O., grade A, surgeon, Trinidad.
O'Shaughnessy, J. D., M.B. Dubl.: M.O., Malaya.
Patton, G. Q., M.R.C.S., D.T.M. & H.: M.O., Northern Rhodesia.
Ramsay, Robert, M.B. Glasg.: asst. director of medical services, Gold Coast.
Saunders, G. F. T., M.D. Dubl.: specialist, Gold Coast.
Slessor, R. S., M.B. Aberd.: senior M.O., Falkland Islands.
Watt, Anne, M.B. Glasg.: lady M.O., Malaya.

Births, Marriages, and Deaths

BIRTHS

Adams.—On June 16, in Belfast, the wife of Dr. G. F. Adams—a daughter.

Belsey.—On June 15, at Bristol, the wife of Mr. Ronald Belsey, F.R.C.S.—a daughter.

Bird.—On June 25, at Reading, the wife of Dr. J. G. Bird—a daughter.

Dawes.—On June 20, at Headington, Oxford, the wife of Dr. Geoffrey Dawes—a son.

Dunn.—On June 24, at Salisbury, the wife of Dr. G. N. Dunn—a son.

Horsnell.—On June 19, at Watford, the wife of Dr. Maxwell Horsnell—a daughter.

Knowles.—On June 20, at Epsom, the wife of Dr. Colin Knowles—a daughter.

Lawless.—On June 18, in London, the wife of Dr. D. J. Lawless, O.B.E.—a daughter.

Macmillan.—On June 21, in Toronto, Canada, the wife of Dr. R. L. Macmillan—a son.

Maisey.—On June 22, in London, the wife of Major C. W. Maisey, R.A.M.C.—a son.

Martin.—On June 16, in London, the wife of Dr. T. D. M. Martin—a daughter.

Mayer.—On June 18, the wife of Mr. J. H. Mayer, F.R.C.S.—a son.

Miller.—On June 22, at Rugby, the wife of Dr. Peter Miller—a daughter.

Parsons.—On June 25, at Weymouth, the wife of Dr. G. Parsons—a son.

Shorvon.—On June 17, in London, the wife of Dr. H. J. Shorvon—a son.

Waller.—On June 19, at Harrow, the wife of Dr. H. Noel Waller—a daughter.

Wood.—On June 21, at Ealing, the wife of Dr. E. J. Wood—a son.

MARRIAGES

Barnard—van der Haas.—On June 22, at Rotterdam, Harold Faraday Barnard, M.B., to Floor van der Haas.

Groves—Kemball.—On June 11, in London, John Nixon Groves, D.S.O., M.B., to Anne Leslie Kemball.

DEATHS

Barlee.—On June 25, at Guildford, Hobart John William Barlee, M.D. Lyons, aged 79.

Morris.—On June 11, killed at Sedjera, Upper Galilee, Israel, Isaiah Morris, M.C., M.R.C.S., D.C.H., aged 30.

Stephenson.—On June 16, at Monkstown, County Dublin, Edward Francis Stephenson, F.R.C.S.I., F.R.C.P.I., D.P.H.

Thomas.—On June 16, Leonard Kirkby Thomas, M.R.C.S., aged 76

Thorpe.—On June 23, in London, Vidal Gunson Thorpe, O.B.E., M.R.C.S., surgeon rear-admiral, R.N., aged 84.

Wigg.—On June 22, James Wigg, L.R.C.P., aged 88.

Windsor.—On June 22, at Royston, Herts, Charles William Windsor, M.A., M.D. Camb.

Notes and News

R.A.M.C. JUBILEE

To mark the 50th anniversary of the foundation, in 1898, of the Royal Army Medical Corps, the R.A.M.C. Association has compiled a jubilee scrapbook,[1] the profits from which are to be devoted to the Corps' War Memorial Fund. Carefully conceived and amply illustrated, this little book gives vivid glimpses of the Corps at work and at play, in peace and in war. For the buyer as well as the fund the half-crown surrendered for a copy will be money well spent.

SUPPLEMENTARY OPHTHALMIC SERVICES

In the light of the report of the Spens Committee on the remuneration of consultants and specialists, the fee for the testing of sight in the Supplementary Ophthalmic Service by medical practitioners having the prescribed qualifications will be £1 11s. 6d. a case, on the understanding that the practitioner will be responsible for providing all necessary premises and equipment.

A JUBILEE

Medical-school journals are nearly always good reading, and occasionally they are something more. The *Gazette* of Manchester University Medical School, which has just achieved its 50th anniversary, is a particularly handsome and well-served journal, printed well on plenty of good paper and carrying well-illustrated and informative clinical articles, historical essays, reports of meetings, and book reviews, as well as the usual quota of obituaries, light verse, howlers, and professorial witticisms. In the jubilee number, with its gilded cover, Dr. E. Bosdin Leech recalls the long roll of editors, the changes of cover design, and the brilliant illustrators—including Henry Lamb—who have from time to time adorned its pages, while Mr. W. J. Metcalfe writes of the lively and informal meetings of the Owens College Medical Students' Debating Society, where smoking was allowed, and subjects ranged from nurses (treated seriously) to ghosts, hypnotism, infant mortality, the reform of the stage, the effect of dress on morals, mendelian inheritance, and the benefits of alcoholism and disease on the race. An article on hand infections, written by Mr. Harold Bolton, F.R.C.S., and Mr. R. P. Jepson, F.R.C.S., and beautifully illustrated by photographs, gives this jubilee number special distinction.

PROFESSIONAL AID

The child who makes a bad start in a subject—often because he was ill during the first term it was taught, or because he was grounded by a poor teacher—never catches up unless he is given a little individual help. Problems mount with every fresh lesson, and his ability to overcome his difficulties wanes even as they pile up on him. This is also the fate of some able people who, often through no fault of their own, get into financial difficulties. Timely help, sometimes even quite a small amount of help, would put them on their feet; but with no-one to turn to they are overwhelmed. It is to relieve such people that the Professional Classes Aid Council[2] was founded. Composed of representatives of almost all the great professional bodies, it works in close association with their funds and institutions; but many of these funds are restricted to certain groups, and some professional people are excluded from them. The council gives special help to such cases, and also to other suitable non-professional people. Immediate help is given when necessary but the council's main task is to set professional men and women on their feet and see them through their difficulties. The annual report for 1947–48 shows how effective such aid can be. Generous help is given with the education and training of young people: during the year grants were made to 106 children. As an example, a boy of 17 whose parents had both broken down in health was helped through the last year of school, and has now won a scholarship which will cover his training as a doctor for the next five years. Annual grants are made to some old people, and the income of a special fund is kept for this purpose. In all £12,817 was spent last year in relief.

VOLUNTARY HELP FOR HOSPITALS

In its memorandum "Personal Support for Hospitals in the National Health Service" the British Hospitals Association suggested that after July 5 there will be undiminished opportunity for voluntary services and personal interest and support. In a further memorandum[1] the association urges the establishment of a league of friends for each local hospital or group of hospitals: such a league, it is believed, would make a suitable assembly point for voluntary workers.

FOOD FOR THE CONVALESCENT

One of the chief pleasures of the convalescent is in eating. Like the traveller on a long sea voyage he has little to entertain him except meal times, and if he is to gain weight and vigour quickly he should not be disappointed. A new *Memorandum on Catering for Convalescent Homes*,[2] published by King Edward's Hospital Fund for London, gives some first-class advice on catering, staffing, equipment, service, the planning of dining-rooms, and prevention of waste, and carries a section of menus and recipes. The material is largely drawn from the memoranda on hospital diet published by the fund in 1943 and 1945, but is more brief and concise, and it will be welcome to the busiest matron in charge of the feeding of convalescents.

OPTION IN SUPERANNUATION SCHEME

A leaflet (S.D.D.), obtainable from executive councils, gives details of the choice open to doctors and dentists in the new service who already hold insurance policies providing for themselves on retirement or for their wives and dependants on death. Those with cover broadly equivalent to that of the National Health Service superannuation scheme may remain outside the scheme and receive instead an amount equal to 8% of their net remuneration (i.e., their gross remuneration for general medical or dental service, less a percentage for practice expenses) towards the premiums. The condition is that the premiums on endowment or deferred annuity policies maturing at the age of 60 or later must amount to at least £150 per annum. Where the annual premiums are between £50 and £150 the practitioner will be given an opportunity of taking out additional policies to bring them up to £150.

Doctors wishing to exercise the option must apply in writing to their executive council before Oct. 4.

University of London

Dr. R. S. Stacey has been appointed to the university readership in therapeutics at St. Thomas's Hospital medical school.

Dr. Stacey, who is a graduate of Cambridge University, qualified from St. Thomas's in 1930, and two years later he became first assistant to the professor of medicine. In 1935 he took up his present appointments as professor of pharmacology and therapeutics in the Royal Faculty of Medicine of Iraq, and physician to the Royal Hospital, Bagdad.

University of Bristol

At recent examinations the following were successful:

M.D.—G. H. Wakley.

M.B., Ch.B.—Barbara Brosnan, Suzanne K. R. Clarke, R. S. G. Davies, C. C. Downie, M. J. Dunn, Molly I. Govier, Pamela I. Hannaford, A. H. Levy, Jenny Pym, F. A. A. Rugget, B. F. Vaughan, George Winternitz, R. H. Wood; and in group II (completing examination) Elizabeth H. Chard.

D.R. (Part II).—A. A. G. Flemming, F. A. Hanna.

D.P.H. (Part II).—R. G. Brennan, J. B. M. Davies, D. M. M. Jones, E. W. Moore, William Nicol.

D.P.M. (Part II).—W. L. Jones, Ronald Magee, J. R. Stuart.

Lady Tata Memorial Trust

The trustees of the fund have made the following awards for research in blood diseases, with special reference to leukæmia, in the year beginning Oct. 1, 1948:

Grants for research expenses and assistance:

- Dr. Marcel C. Bessis (France).
- Dr. Jørgen Bichel (Denmark).
- Dr. Pierre Cazal (France).
- Dr. Johannes Clemmesen (Denmark).
- Dr. P. A. Gorer (Great Britain).
- Dr. Andrew Kelemen (Hungary).
- Dr. Edith Paterson (Great Britain).
- Prof. Edoardo Storti (Italy).

Scholarships (for whole-time or part-time research):

- Dr. Simon Iversen (Denmark).
- Dr. C. F. M. Plum (Denmark).
- Dr. G. H. R. Tötterman (Finland).

---

1. Jubilee Scrapbook of the Royal Army Medical Corps: 1898–1948. Compiled by the R.A.M.C. Association. Pp. 41. Obtainable, 2s. 9d., post free, from Messrs. Gale and Polden Ltd., Wellington Press, Aldershot.
2. Annual Report, 1947–48. Obtainable from the secretary of the council, 20, Campden Hill Square, London, W.8.

---

1. Local Organisations and Funds in Aid of a Particular Hospital or Group of Hospitals. Memorandum published by the British Hospitals Association, 39, Green Street, London, W.1.
2. Obtainable from Geo. Barker & Son, Furnival Street, London, E.C.4. Pp. 32. 6d.

Royal Institute of Public Health and Hygiene

Sir Lionel Whitby will deliver the Harben lectures for 1948 at the institute, 28, Portland Place, London, W.1, at 3 P.M. on Dec. 7, 8, and 9. He has chosen as his subject Hæmopoiesis.

Royal Faculty of Physicians and Surgeons of Glasgow

At a recent examination for the diploma in industrial health of the faculty the following were successful:

Roy McL. Archibald, J. H. Bell, J. H. Chambers, J. L. Fyfe, Duncan Livingstone, Edward Livingstone, Duncan MacInnes, D. A. MacLean.

British Standards Institution

The annual general meeting of the institution will be held on Wednesday, July 21, at 3 P.M. at the Institution of Electrical Engineers, Savoy Place, London, W.C.2.

International Scientific Film Congress

The second congress of the International Scientific Film Association will be held in London from Oct. 4 to 11. Further details may be had from the Scientific Film Association, 34, Soho Square, London, W.1.

Factors Concerned in Vision, Light, and Seeing

Mr. Matthew Luckiesh, director of the lighting research laboratory, General Electric Company, Cleveland, U.S.A., will speak on the above subject at the London School of Hygiene, Keppel Street, W.C.1, on Wednesday, July 14, at 2 P.M.

Meeting of Child Psychiatrists

The child psychiatry section of the Royal Medico-Psychological Association are holding a meeting at 1, Wimpole Street, London, W.1, on Friday, July 9, at 4.15 P.M., when a paper will be read and a film shown on Grief—a Peril in Infancy. Members of the British Pædiatric Association and the Section of Pædiatrics of the Royal Society of Medicine are invited to attend.

London County Council

Major-General J. P. Helliwell, consulting dental surgeon in the public-health department, has retired owing to ill health. The first to hold this post under the council, he was also the first chief of the Army Dental Corps. He was a member of the Teviot Committee on dentistry which reported in 1946.

Dr. Dorothy Egan, an assistant medical officer in the public-health department, has been promoted to be a divisional medical officer.

Ross Jubilee Exhibition

To mark the 50th anniversary of the discovery of the transmission of malaria by mosquitoes, finally completed by Ronald Ross on July 9, 1898, an exhibit has been prepared showing the history of developments in malaria control, and examples of the present stage of malaria control in many parts of the world. The exhibit will be open to the public at the London School of Hygiene, Keppel Street, W.C., from 11 A.M. to 4 P.M. from July 6 to 9.

British Delegation to World Health Assembly

Sir Wilson Jameson, chief medical officer of the Ministry of Health, headed the United Kingdom delegation to the first World Health Assembly when it opened in Geneva on June 24. His place as chief delegate is now being taken by Dr. Melville Mackenzie, also of the Ministry. Other delegates include Dr. Wilson Rae (Colonial Office) and, for part of the time, Dr. P. G. Stock and Dr. R. H. Barrett (Ministry of Health), Mr. George North, LL.D. (Registrar-General), and Dr. Percy Stocks (General Register Office).

Refresher Courses in Tuberculosis

On behalf of the Tuberculosis Educational Institute, the National Association for the Prevention of Tuberculosis will hold the following courses during 1948: Radiology in Connexion with Tuberculosis and Chest Diseases, at Leeds University, Sept. 20–22; Treatment of Non-pulmonary Tuberculosis including Lupus, at Lord Mayor Treloar Cripples' Hospital, Alton, Hants, Oct. 5–7; clinical courses, at the Cheshire Joint Sanatorium, Market Drayton, Salop, Oct. 26–28, Nov. 23–25, and Dec. 7–9. Further particulars may be had from the secretary of the N.A.P.T., Tavistock House North, London, W.C.1.

King's College Hospital

A memorial lecture has been founded in memory of Thomas Percy Legg, surgeon to the hospital from 1910 to 1930. A scholarship in cardiology has also been endowed to commemorate Harold Waterlow Wiltshire, physician to the hospital from 1910 to 1925.

Speech Therapy Conference

The College of Speech Therapists is holding an international conference at 1, Wimpole Street, London, W.1, from Sept. 20 to 24. The speakers will include Dr. Leopold Stein (Vienna), Dr. Macdonald Critchley, and Dr. Mildred Creak, and there will be discussions on the Emotional Background of Disorders of Speech, and Speech Disorders Arising from Head Injuries. Further information may be had from the conference secretary, 68, Queen's Gardens, W.2.

International Refugee Organisation

The medical staff of the preparatory commission (PCIRO) is as follows:

HEADQUARTERS, GENEVA

Director of health: Dr. R. L. Coigny (Paris).
Medical consultant: Dr. H. Kennedy (Belfast).
Medical consultant: Dr. J. B. Petrie (Aberdeen).
Chief nurse: Miss S. J. Haines (Australia).
Chief nutritionist: Miss C. Hill (U.S.A.).

CHIEF MEDICAL OFFICERS

Germany (U.S. Zone): Dr. L. Findlay (Aberdeen).
Germany (British Zone): Dr. R. F. Walker (Belfast).
Germany (French Zone): Dr. R. E. Dax (Paris).
Austria: Dr. E. S. Meyers (Australia).
Italy: Dr. C. T. Jones.

Lieut.-Colonel Joseph Caplan, R.A.M.C., has been awarded the Order of El Maaref (Third Grade) by the King of Egypt for his services in connexion with the suppression of malaria.

Diary of the Week

JULY 4 TO 10

Monday, 5th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
5 P.M. Mr. R. Weedon Butler: Acute Hæmatogenous Osteomyelitis.
6.15 P.M. Mr. A. D. Marston: History of Anæsthesia.
WESTMINSTER HOSPITAL, Horseferry Road, S.W.1
5.30 P.M. (Meyerstein theatre.) *Clinico-pathological demonstration on Subacute Bacterial Endocarditis.*
WEST LONDON MEDICO-CHIRURGICAL SOCIETY
7.45 P.M. (South Kensington Hotel, 41, Queen's Gate Terrace, S.W.7.) Debate that Capital Punishment is Bad Prophylaxis.

Tuesday, 6th

ROYAL COLLEGE OF SURGEONS
5 P.M. Mr. John Charnley: Fractures of the Forearm Bones.
6.15 P.M. Dr. John Gillies: Anæsthetics for Operations on Cardiovascular Conditions.

Wednesday, 7th

ROYAL COLLEGE OF SURGEONS
5 P.M. Mr. G. R. Girdlestone: Pott's Disease and Pott's Paraplegia.
6.15 P.M. Dr. A. C. Forrester: Anæsthesia for the Outpatient.
ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION
10.15 A.M. (1, Wimpole Street, W.1.) Annual meeting.
11 A.M. Dr. W. Rees Thomas: Presidential address.
2.30 P.M. (11, Chandos Street, W.1.) Dr. J. B. S. Lewis, Dr. W. J. T. Kimber, Miss R. S. Addison: Training and Scope of Psychiatric Social Workers in Relation to Adults.

Thursday, 8th

ROYAL COLLEGE OF SURGEONS
5 P.M. Dr. Richard B. Cattell (Lahey Clinic): Carcinoma of the Pancreas. (Surgery lecture.)
ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION
8 P.M. (11, Chandos Street, W.1.) Dr. J. Carse, Dr. T. J. Hennelly: Planning a Psychiatric Inpatient Service.

Friday, 9th

ROYAL COLLEGE OF SURGEONS
5 P.M. Mr. K. I. Nissen: Non-tuberculous Affections of the Hip-joint in Childhood and Adolescence.
6.15 P.M. Dr. Geoffrey Organe: Assessment of Anæsthetic Risk.
GUY'S HOSPITAL, S.E.1
5 P.M. Dr. E. B. Astwood (Harvard): Medical Treatment of Hyperthyroidism. (Addison lecture.)
ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION
10.30 P.M. (11, Chandos Street, W.1.) Dr. W. McCartan, Dr. J. Ferguson, Dr. K. C. Bailey: Relation of the Mental Hospital to the Community.

GAMMA-GLOBULIN IN THE PREVENTION AND ATTENUATION OF MEASLES

REPORT OF A SUBCOMMITTEE * TO THE BLOOD TRANSFUSION RESEARCH COMMITTEE OF THE MEDICAL RESEARCH COUNCIL

In July, 1943, a litre of normal human serum gamma-globulin antibodies, prepared according to the technique elaborated by Dr. E. J. Cohn at Harvard, was placed at the disposal of the Director of Biological Standards at the National Institute for Medical Research, Hampstead, through the generosity of Dr. Cohn and the American Committee for Medical Research. At that time this material, which had hitherto been produced only at the pilot plant at Harvard, was beginning to be prepared on a large scale for issue to the American armed forces, but the elaborate low-temperature plant required and the large amount of alcohol used in the process made it impracticable to produce gamma-globulin in the United Kingdom during the war. The production of large quantities in the United States was possible because the raw material was a by-product of the manufacture of serum-albumin which was used extensively for transfusion in the Services.

Through the courtesy of our American colleagues we were sent the progress reports,[1] and it was evident from the early trials in the U.S.A. that Cohn's fraction II was a remarkably effective measles prophylactic. (At that time electrophoretic analysis showed fraction II to contain 87% of gamma-globulin, and by a later improvement in preparation this figure was raised to 98%.) Accurate dosage scales had not yet been worked out, but it was apparent that the effective dose was considerably smaller than that of any other known measles prophylactic. Moreover, encouraging results were recorded in the treatment of measles in the early stages, and it was stated that cases in which gamma-globulin had been given at the stage of development of Koplik's spots had developed no rash.

Under the ægis of the Blood Transfusion Research Committee of the Medical Research Council a subcommittee was formed to decide how best to use the sample of American gamma-globulin. Experience with other measles prophylactics had shown that the results were influenced by the age of the patient, the degree and duration of exposure to infection, the duration of the exposure-injection interval, the dose, and the stage of the epidemic in which the material was injected. It was decided to try to assess the value of the new prophylactic in comparison with other preparations whose value in this country was already known, and to this end an experiment was planned in which the whole sample was used in comparative tests with convalescent measles serum. Tests were carried out by members of the committee on children in their homes, in hospitals, and in residential nurseries. In this first inquiry no adjustment of dosage was made for age or body-weight, and the quantities injected for prevention and attenuation were reduced as far as possible in the hope that significant results would be obtained. The results of this experiment are given in part I of this report.

In the summer of 1944 so little measles was occurring in the U.S.A. that difficulty was being experienced by American workers in testing new batches of gamma-globulin produced by commercial firms, and an appeal was made to our committee for assistance in this work. As a result a consignment of 2390 ml. was received from America for testing, this consisting of samples of 15

---

batches prepared by five different commercial firms. Since this shipment of gamma-globulin had been given o the committee for the specific purpose of testing each batch for the presence of measles antibodies, an entirely different method of working from that used in the previous experiments had to be adopted. Moreover, it was found advisable at this stage to adopt a dosage imilar to that which was then in use in America and to adjust the quantity injected to the patient's body-weight. An interim report on these batches of gamma-globulin, ogether with the relevant record cards, was submitted o our American colleagues in November, 1945. The ests showed that one batch was deficient in protective antibodies, but that the remainder were satisfactory n this respect. A summary of the results obtained in hese trials forms part II of this report.

In July, 1946, Dr. C. A. Janeway, who was closely associated with Dr. Cohn in the early work on gamma-lobulin, sent to this country a further 2500 ml. of this prophylactic. The expiry date of this material was May, 1946, which showed that it had been prepared in May, 1945. Studies were being carried out in America on similar outdated material, and a request was made that collateral studies should be made in Britain to determine whether, as earlier trials had suggested, the material retained its potency considerably longer than the period indicated by the official expiry date. Experience with this outdated material forms part III of this report.

The committee kept the various trials under fairly close personal supervision, though the tests were done in a number of different environments. Some of the tests were made in Glasgow and district and the rest in the London area. Many observations were made in home contacts when there was evidence of exposure of susceptible children to a definite case of measles; others were made in fever hospitals when cases of measles occurred in wards containing children with other infectious diseases, in residential schools, and in residential nurseries.

Attention was focused on the necessity for including in the survey only children who had not had measles in the past and were now exposed to an undoubted case. It was realised that no significant results could be obtained if the exposure-injection interval was more than five or six days, and this fact was kept in mind in the selection of measles outbreaks for inclusion in the trials.

Another factor that had to be considered was the temporary nature of the immunity resulting from serum or globulin injections. A child may be protected by serum from one exposure but may contract measles from a later exposure. The period of observation was therefore limited to the first three weeks after injection. In one outbreak in a preparatory school, included in this report, convalescent measles serum or gamma-globulin was given to 24 contacts within two days of

first exposure. None of these boys developed measles during the next three weeks, and the results have therefore been recorded as successful. Later, however, 22 of the boys developed measles 26–49 days after injection, some of them having unmodified attacks.

The injections were given intramuscularly and no untoward results were noted.

PART I: COMPARATIVE TESTS OF THE POTENCY OF GAMMA-GLOBULIN AND CONVALESCENT SERUM

This part of the inquiry had the limited objective of comparing the value of the American gamma-globulin with that of measles prophylactics already in common use in Great Britain. Convalescent measles serum was chosen for the comparative tests as being the most reliable of the existing prophylactics, and a single batch of dried convalescent serum was reconstituted and used as the control material.

The American protocols suggested that, if gamma-globulin was given in full dosage, a very high degree of protection could be expected. Full protection of the experimental herd with gamma-globulin would not have furthered the purpose of the trial. It might have shown that gamma-globulin was a powerful prophylactic and perhaps that it was better than convalescent measles serum, but it would not have shown how much better one prophylactic was than the other. It was therefore decided that wherever possible the dosage of both prophylactics should be reduced to the level at which success or failure hung in the balance. It was left to the medical officer carrying out the trial to decide when this could be done with safety. It was agreed generally that no adjustment of dosage was to be made at this stage for age or body-weight, but that the aim should be to use the following doses when possible :

For attenuation :	Convalescent measles serum ..	2·5 ml.
	Gamma-globulin	1·2–1·5 ml.
For protection :	Convalescent measles serum ..	5·0 ml.
	Gamma-globulin	3·5 ml.

It was impossible to adhere to this dosage scheme throughout, but it was adopted in the large majority of cases. Tables I and II show the doses used and the numbers of children at each age in hospitals, schools, and nurseries, and the patients' homes.

To eliminate as far as possible the effect of differing degrees of exposure and of different time and place, trials were limited to instances in which at least 2 susceptible contacts had been exposed to the same infection for the same period, and convalescent serum and gamma-globulin were each given to an equal number of contacts. The serum and globulin groups in each test contained roughly the same number of children of each age-group ; 136 contacts were given convalescent measles serum and 139 received gamma-globulin.

Results.—It should be remembered that the aim of this test was neither protection nor attenuation but comparison of the two prophylactics. The numbers are small, and percentage figures based thereon must be accepted with reserve, but the comprehensive percentage results shown in table III are instructive. For all doses taken together there is a significant difference between the percentage protected by gamma-globulin (82·7) and by convalescent serum (70·6).

TABLE IV—RESULTS WITH DIFFERENT BATCHES OF GAMMA-GLOBULIN

Aim : prevention

Maker	No. of children	Average measles	Mild measles	No measles
A	6	..	..	6
B1	2	..	..	2
B2	6	..	..	6
B3	11	..	..	11
C1	2	..	..	2
C2	2	..	..	2
C3	9	..	..	9
C4	1	..	1	..
C5	5	..	..	5
C6	15	..	3	12
D1	21	1	1	19
D2	28	2	10	16
E1	6	..	..	6
E2	9	..	1	8
Total	123	3	16	104

Perhaps the most instructive group of cases was that in which the smallest doses were used. From tables I and II it is seen, from the high proportion of cases in which attenuation as opposed to protection was attained with the smallest doses, that the doses used on these children (almost all of whom were under 5 years of age) were somewhere near the minimal protecting dose. At this age we can therefore regard a dose of 2·5 ml. of convalescent measles serum as roughly equivalent to a dose of less than 1·2 ml. of gamma-globulin.

Thus the general conclusion from this trial is that the gamma-globulin used was rather more than twice as potent as the sample of convalescent measles serum.

PART II: TRIALS OF GAMMA-GLOBULIN FROM DIFFERENT MANUFACTURERS

When the request was received from American workers to help them in carrying out trials of commercial gamma-

globulin the tests described in part I of this report had been completed, and the standard of performance to be expected in this country from Cohn's fraction-II was known. Since our American colleagues had decided to abandon the "flat dose" in favour of a dose adjusted to body-weight, and since it was necessary for the British trials to conform as far as possible to those in progress in America, the new dosage was adopted in our trials. The dose recommended for prevention was 0·1 ml. per lb. body-weight, given intramuscularly as soon as possible after first exposure to infection.

In table IV the results are tabulated according to the batch and manufacturer. The results from D2 fell well below the standard attained by all the others. Table V shows the results obtained in the different environmental communities studied, omitting the defective batch D2. Table IV shows that the over-all rate of success in the prevention of measles was 84·5%, and when the defective batch D2 was omitted the figure was 92·6%. When the defective batch is omitted, either prevention or attenuation was obtained in 94 out of 95 injected contacts (table V).

A portion of the supply of gamma-globulin used in this part of the trials was unused at the end of the measles epidemic. This was used in the same dosage in the following year, by which time it had passed its expiry date. It was given to 36 children, with the object of prevention, with complete success in all cases. An attempt to attenuate measles in 7 other children led to the protection of 5 and the development of a modified attack in 2.

PART III: USE OF OUTDATED GAMMA-GLOBULIN IN PREVENTION AND ATTENUATION

Apart from their scientific interest the results of this part of the inquiry are of considerable administrative importance. If any measles prophylactic is to be used on a large scale, very large quantities must be available for issue when an epidemic begins. The extent of a measles epidemic cannot be forecast with accuracy, and the demand for prophylactics is even more difficult to estimate. It is of some importance to know if stocks that are not used during an epidemic can be safely used in the following year. This report goes some way to answer this question.

This aspect of the subject has already been mentioned in part II, where it was shown that outdated material from different batches was still active.

The gamma-globulin used in this part of the inquiry, which was for the most part given in the winter of 1946–47, had been prepared in May, 1945, and bore an expiry date of May, 1946. The dosage adopted was similar to that in part II. The results, summarised in table VI, show that, when attenuation was the aim, the result was 40% attenuated and 58% protected—a total of 98% either protected or attenuated. When protection was the aim, the result was 81% protected and 18% attenuated—a total of 99% either protected or attenuated.

That the attempt at protection was successful in only 81% of cases may well be explained by some deterioration of the gamma-globulin arising from its age. It should be noted, however, that of the 156 children in whom protection was sought only 1 showed no benefit from the injection. When attenuation was sought, the outcome was more satisfactory (98% successful), which seems to indicate that if any deterioration of gamma-globulin did occur with the passage of time it was slight.

CONCLUSIONS

The prophylactic under examination in the trials described in this report was human-serum gamma-globulin prepared in America by the process devised by E. J. Cohn. The small quantity available has limited the scope of the experiments, but the following conclusions may be stated:

1. Gamma-globulin, prepared by Cohn's method, contains measles antibodies in high concentration.

2. The volume of gamma-globulin required for the prevention and attenuation of measles is about half the volume of convalescent measles serum required.

3. Though superior in action to convalescent measles serum, gamma-globulin in the doses used in these trials did not give full protection in all cases. Some degree of attenuation was, however, obtained in almost all cases.

4. Though the potency of solutions of gamma-globulin cannot be quantitatively estimated, the samples examined nearly two years after their preparation showed high protective and attenuating properties, differing but little from others which had been in circulation for a shorter time.

5. No local or general reactions followed the injection of gamma-globulin.

OPERATIONS FOR HERNIA

TECHNIQUE OF NYLON DARN

A REVIEW of the results of hernia surgery during the late war has revealed an alarming number of recurrences (Edwards 1943), and this disclosure has led to a reconsideration of the whole subject of hernial repair. It is clear, from an analysis of cases in the Services, that many of the recurrences were the result of bad surgery by inexperienced operators. Others have thrown a share of the blame on our inadequate knowledge of the mechanism of the inguinal canal; and, as new interpretations of this mechanism are made, new operations are devised to fit in with these ideas.

It is as well to recall that, by methods in use long before the war, the worst of herniæ were capable of repair, and that herniæ recurrent for the fourth or fifth time have been eventually cured by an operation properly planned and performed. There appears to be an increasing tendency to condemn the Bassini operation in its original form, and an inclination, in larger herniæ at any rate, to use some form of darning or filigree operation. For the repair of weaknesses and deficiencies in our hard-worn fabrics no method has been so successful as darning, provided the darn is woven firmly and without tension into sound surrounding material.

Silk, thread, silver wire, and fascial strips have all been used with great success for the repair of weaknesses in the inguinal canal and other sites. We believe that the material used to lace the deficient region matters less than the care of the operator and his adherence to a few guiding principles. When a darn is made in the tissues, a mesh is formed which is invariably filled by fibrous tissue. In the production of fibrosis the mesh is the important factor and not the nature of the material used to form the lattice. The end-result of a darn is a buttress across the weak area consisting largely of suture material together with various amounts of fibrous tissue. The effective constituent of the buttress is the suture material; and, though fibrous tissue is laid down and is helpful, it is neither essential nor dependable for permanent repair. Since the buttress is the important factor and not the fibrosis, the most suitable material for a darn is that to which the tissues take most kindly.

The requirements for a lattice are that it should be (1) tailored for the individual, (2) of small mesh, (3) well anchored to surrounding tissues, (4) pliant, (5) productive of a minimal tissue reaction, (6) technically simple to introduce, (7) undisturbed by the misfortunes of sepsis and so suitable for strangulated cases, and (8) a permanency in the tissues and not absorbed or dislodged at a later date. We have found that 'Nylon' satisfies these conditions better than any other material.

We do not present here the results of a late follow-up, for Burdick et al. (1937) showed, in a series of 1485 cases of hernia, that 40% of recurrences occurred after two years, and similarly Block (1933) found, in the cases he investigated, that 34·8% of recurrences occurred after two years. In view of the findings of these and other workers, five years should elapse from the time of operation before it is worth while assessing the cases to obtain an accurate recurrence-rate. As regards immediate healing, half our cases have been seen more than six months after operation, and only in the case of a huge umbilical hernia, which became septic after repair, has there been any sign of a recurrence.

Nylon has been used in operations for hernia by Melick (1942) in 10 cases, and by Haxton (1945), but neither of them has stated his methods. We have evolved a technique which closely simulates the darn with silk used by Ogilvie (1937): but, since we have had to overcome certain difficulties resulting from the nature of the material, we include details of technique. The advantages of nylon as a suture material have been emphasised by other workers to whom Haxton referred, and it was his article which first drew our attention to its merits. We have used nylon for many other purposes, but here we are confining our attention to its use in hernia. The cases treated by three surgeons in the fifteen months up to April 30, 1947, are analysed as follows:

	Simple hernia	*Strangulated hernia*	*Total*
With darn:			
Inguinal	140 (Indirect 116, direct 24)	13	153
Incisional	7	1	8
Umbilical	8	4	12
Total	155	18	173
Without darn:			
Inguinal	21	0	21
Femoral	18	18	36
Total	39	18	57
All cases ..	194	36	230

TECHNIQUE

The inguinal canal is approached through a crease incision. The cremaster muscle is incised and subsequently dealt with according to inclination. In direct herniæ the sac, unless large or funicular, is not excised. Next, the internal ring is examined carefully: where it is fairly well defined and has strong edges it is repaired by interrupted sutures medial to the cord. In large herniæ the ring may be virtually destroyed, and all that is left is a ragged edge of transversalis fascia. In these cases the lower edge of the internal oblique muscle is retracted upwards, and a nylon suture no. 5 on a no. 13 round-bodied half-circle needle is passed through the posterior aspect of the internal oblique muscle and then down to Poupart's ligament, picking up the ragged edges of the transversalis fascia on the way, and back again in a similar fashion, passing once again through the fascia and muscle (fig. 1). This suture is tied firmly, thus tightening the region of the internal ring about the cord, though no attempt is made to force the internal oblique muscle against the inguinal ligament.

The darn is now begun. It consists of two layers between the upper and lower boundaries of the inguinal canal. The suture used is a 40-in. length of no. 5 nylon for the first layer and no. 7 nylon for the second layer, threaded on a small round-bodied half-circle needle. After being threaded through the needle the ends of the suture are knotted together, thus preventing it from becoming unthreaded. The original 40-in. length thus becomes a double length of 20 in. and is darned as such. The first layer of the darn is started by passing the needle through the dense fibrous tissue in the medial aspect of the pubic tubercle, and this stitch is anchored by passing the needle back through the loop formed by the knotted ends (fig. 1). It proceeds as a continuous suture between the lower edge of the internal oblique muscle and the inguinal ligament, and, as in the second layer, the stitches are placed four or five to the inch (fig. 2). This layer is completed when it reaches the internal ring. No attempt is made to approximate the internal oblique muscle to the inguinal ligament, and the chief function of this first layer is to bed the structure down on the posterior wall of the inguinal canal, making ready for the next and more important layer of sutures.

The second layer starts like the first. Below, it picks up the inguinal ligament in between the points occupied by the first layer. Above, it is passed through the rectus sheath medially, and, as the outer end of the canal is approached, the suture passes through the tendinous portion of the internal oblique muscle. It is most important to carry the sutures high up laterally and to make certain that it is the tendinous portion of the internal oblique muscle that is included, so that when strain comes it can be taken by structures well able to deal with it (fig. 3).

When the internal ring is reached, two or three sutures are passed *lateral to the cord, helping to reinforce the inguinal* ring. In most cases this completes the darn; but, where a large defect exists, further diagonally placed sutures are used, interlocking with the vertical ones in a manner similar to that used for darning a sock. All sutures are placed without tension but with no slack. Nylon glides through the tissues most pleasantly and does not stick or drag like thread or silk; hence the tension can be adjusted with great ease. As the end of each suture is reached it is finished by tying two half-hitches (fig. 2). Usually three lengths of 40-in. nylon, doubled, are required, but in large defects as many as six lengths have been used.

After the darn is completed, the cord is allowed to fall back into place. The external oblique aponeurosis is repaired with a single suture of no. 5 nylon. By the bootlace method (fig. 4) a knot in the region of the external ring is avoided. The suture begins on the deep surface so that the knot lies beneath the aponeurosis. Sometimes it is difficult to finish a suture line in this manner, in which case the suture ends may be buried by the method illustrated (fig. 4). Either of these manœuvres, which are applicable in other operations, prevents the ends of the nylon from projecting through the skin later. In thin persons, if the ends are simply cut after knotting and not buried they tend to present beneath the surface, or even to work through the scar and appear like the short bristles of a brush.

Finally the subcutaneous tissue and Scarpa's fascia are closed by interrupted sutures of no. 3 nylon, and *the skin is* closed with Michel's clips, which are removed in three days. In about half these cases a frosting of penicillin and sulphathiazole powder has been dusted over each layer as it is closed.

In other types of hernia orthodox repairs were used with nylon as the suture material, and in large incisional and umbilical herniæ nylon was darned in the aponeurotic tissues across the suture lines.

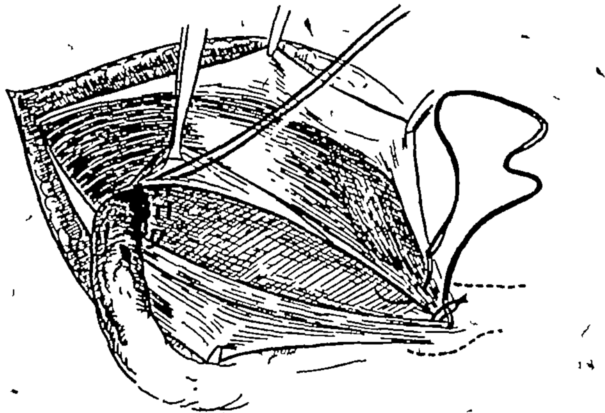

Fig. 1—Suture reinforcing internal ring, and start of darn, showing how knot is anchored.

RESULTS OF WOUND HEALING

Simple Hernia.—In 159 of 161 *simple inguinal hernia* not so much as a stitch abscess developed. The superficial tissues healed without swelling, and the deep tissues showed no sign of serum production. Six *weeks after* operation the skin-crease incisions gave a fine scar in most instances, the skin being supple and the inguinal region firm but not unduly hard. More than half of these darn cases have been seen six months after the operation with no sign in any of them of recurrence or other wound troubles. The 2 cases of sepsis were as follows:

Case 1.—A huge hydrocele on the same side as the hernia was *excised at the* time of the repair of the hernia. A scrotal

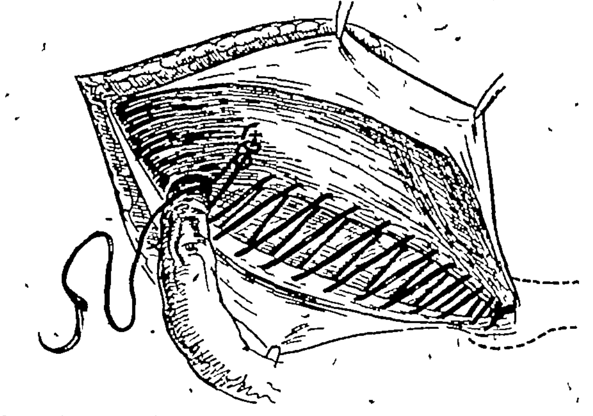

Fig. 2—Loose continuous suture between lower edge of internal oblique muscle and inguinal ligament.

hæmatoma formed and subsequently suppurated, with *discharge from the inner end of the incision, Staph. aureus* being cultured. The inflammation rapidly subsided, and the wound healed in sixteen days from the time of operation, giving no further trouble. The repair was sound six months after operation.

Case 2.—This was the only instance of infection of the repaired tissue. On the sixth day after inguinal darn the wound looked red and on the eighth day a heavy discharge escaped. For a further ten days discharge continued, *after* which the wound healed. The repair was to all *appearances* unaffected by the sepsis when seen three months after *operation*. In this instance neither sulphonamide nor penicillin was used at the time of operation or in the treatment of the infection.

There was 1 case of sepsis in 7 cases of *simple incisional hernia*:

Case 3.—About 4 yd. of nylon was used to darn a large upper abdominal defect. Owing to inadequate suturing of the cutaneous flap, a pool of serum formed which discharged from the lower end of the wound three weeks after operation Healing proceeded slowly until only a small cavity at the lower end of the wound remained. This cavity was laid open, there being no sign of the nylon, which was completely covered by granulation tissue. Subsequently, wound healing progressed in the usual way with a saucerised wound, the final result being firm union. At no time was there extrusion of any nylon. Neither penicillin nor sulphonamide was used in the treatment of this wound. Proteus was the only organism grown from the wound.

In 8 cases of *simple umbilical hernia* there was 1 case of sepsis:

Case 4.—A huge deficiency in an extremely obese woman weighing over 20 st. Several yards of nylon was darned across a Mayo overlap repair. The extensive wound suppurated on one side, *Bact. coli* and β-hæmolytic streptococci being cultured from the discharge. This wound continued to discharge until a small cavity was treated by saucerisation, after which the deficiency soon healed by granulation. There was no sign of an attempt of the tissues to extrude the nylon. This wound had been dusted with sulphanilamide at the time of the repair, but no chemotherapy was used to treat the subsequent infection. The hernia recurred at the site of wound sepsis.

In 18 cases of *simple femoral hernia* no sepsis developed

Strangulated Hernia.—In 5 cases the patients died within six days of operation; since there was not time enough for wound assessment they are not included in our figures. Of the remaining 36 cases 2 developed sepsis (1 of 13 inguinal and 1 of 18 femoral) as follows:

Case 5.—After an enormous strangulated inguinal hernia had been operated on, a hæmatoma of the scrotum became infected and a scrotal abscess formed. It was not observed early in the convalescent *home to* which the patient had been sent, and the abscess became thickly encapsulated A discharge subsequently appeared from the inner end of the incision, *Bact. coli*, proteus, and *Staph. aureus* being cultured from it.

It was necessary to drain the abscess by scrotal incisions, and at this second operation it was seen that the tissues in the region of the darn had firmly healed and the infection had not disturbed them. Owing to the thick wall of the abscess the scrotum took till ten weeks after the operation to heal. The inguinal repair was not disturbed by the adjacent infection.

Case 6.—After a hernia containing gangrenous bowel had been repaired, the wound broke down on the fifth day and discharged for six days before it healed. No subsequent weakness was found three months after operation.

There was no sign of weakness of the wound after operation on any strangulated hernia.

Comment.—The rarity of sepsis in hernia wounds sutured with nylon confirms our experience of nylon in septic wounds. We have used nylon to close in layers, with the support of a dusting of a sulphonamide powder in each layer, many infected wounds, as in appendicitis with general peritonitis, even when these wounds have been bathed in pus. In spite of the presence of infection some hundreds of cases healed by first intention. In 5 cases the wound became infected, and all except 1 healed within three weeks. In one child, two small knots were extruded before the wound healed. In the only case which did not heal—a bowel resection for carcinoma with a grossly infected wound—a sinus formed in relation to a large knot; when the small cavity was laid open and this knot excised, the wound healed by granulation.

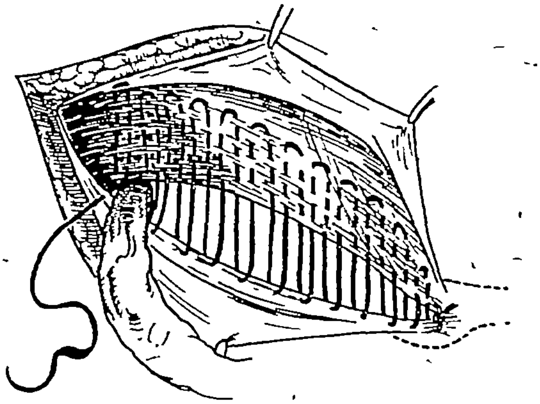

Fig. 3—Second layer of continuous suture, passing through rectus sheath medially and tendinous portion of internal oblique muscle laterally.

In a few early cases in which we used nylon for suture of aponeurotic layers the ends pointed upwards beneath the wound and even worked their way through it. It was necessary to snip away the offending spikes in 2 cases. We have described above how this difficulty is overcome.

DISCUSSION

Repair of herniæ by darning with unabsorbable material has on the whole been followed by good results. The various materials used in the past have both good and bad qualities, but the main advantage of them all is that they form a lattice which resides in the tissues as a permanent shield to a weak area. Nylon has proved to be a highly satisfactory substance with which to form this lattice.

Silk has been in and out of favour for thirty years, its main drawback being the liability to sepsis of the tissues in which it is buried en masse. Ogilvie (1937) and Maingot (1941) reported excellent results with it in civilian use, but others have been troubled by primary sepsis and by sinus formation persisting until the fibres are extruded or removed. In comparison our nylon cases show a very low incidence of sepsis and, when it did develop, there was no attempt at mass or partial extrusion of the suture, but rather was there granulation and healing over the nylon fibres. Neither has there been any sign of late extrusion of the lattice with sinus formation, as described by Edwards (1943) as a frequent occurrence with silk after many of his own operations and those of others on Service patients. This capacity of nylon to withstand sepsis probably results from its monofilamentous, non-irritative, and resistant nature. Silk can harbour organisms in the interstices of its fibres, and the fibres can be attacked and partly digested by products of inflammation. The need for strict exclusion of infection from wounds in which silk is used as a darn calls for extremely careful wound management and a no-touch technique. Though ordinary aseptic precautions were taken in this series of nylon cases, in no instance was the no-touch technique used, fingers being as often in the wound as out of it. We have already mentioned the ease with which nylon glides through the tissues, in marked contrast to the occasional tug which is necessary to drag silk through a stitch hole.

Much the same remarks apply to thread as to silk.

The silver-filigree operation undoubtedly gives excellent results in some hands and is especially valuable for direct herniæ, as Cole (1941) showed. But it is not tailored for the individual like a darn, and Cole admits to the weakness of the medial angle by the edge of the rectus muscle, through which have occurred the few recurrences with which he has had to contend. A darn which starts well over the rectus sheath protects this weak area. Cole also mentions a serous discharge from the wound in some cases, usually about the seventh day. This has not been seen in our nylon cases. Silver wire resembles nylon in that it is monofilamentous, and though silver may irritate the tissues enough to produce a serous exudate it does not appear to encourage early or late sepsis or extrusion. Cole says: "In my experience *infection compelling removal or causing extrusion of filigree is unknown*, and I have failed to trace such an occurrence either by reference or report at the Seamen's Hospital. The same claim cannot be made for silk or fascia by the most ardent advocates."

Fascial-graft repair has given good results in some hands, as instanced by Williamson (1941) and D. C. Corry (personal communication). Others, such as Burdick et al. (1937), Gray (1940), and Wakeley (1940), have been dissatisfied with it and have had a high rate of recurrence. At operation for recurrences after fascial darn they have been unable to find the fascial sutures, a mass of fibrous tissue only being evident, the penalty possibly of relying on fibrous tissue rather than on a permanent shield in the tissues such as the nylon darn supplies. But in the hands of those who have produced good results with fascia there still remain certain objections. There is the necessity to go to the thigh for the

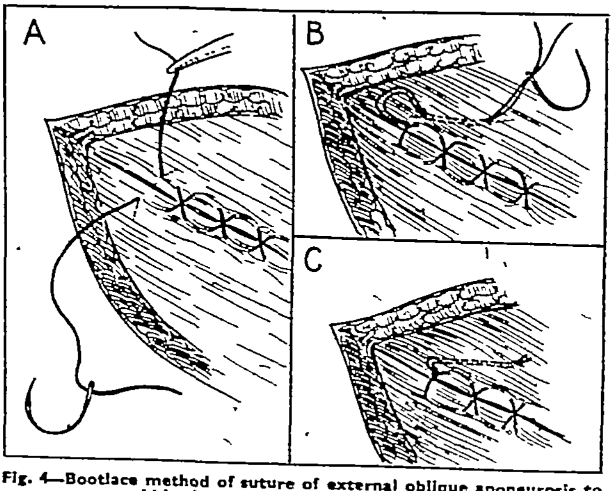

Fig. 4—Bootlace method of suture of external oblique aponeurosis to avoid having knot near external ring.

fascia, and, whether it be cut by fasciotome or open operation, a few cases show thigh disability for some time, and an occasional case even develops an ugly muscle hernia. This objection is a strong one in people who can claim pensions, such as Service personnel. Burdick et al. (1937) pointed out the damage and weakening of Poupart's ligament due to the large holes caused by the needle used to carry the fascia, leading sometimes to a slight recurrence in that region. In some patients with direct herniæ the fibrous tissues of the body are deficient and the fascia may be of poor quality and doubtful strength. The frequency of sepsis in fascial darns is high in some reports and low in others; but, if sepsis does develop, the repair is very liable to be destroyed and recurrence results (Williamson 1941).

The other objections to fascia are technical. The darn with fascia is not easy to perform, being seldom done efficiently in under 45 min. If bilateral cases have both sides treated at one session, it means a long operation. Beckman and Sullivan (1939), with an experience of 2000 cases of hernia, state that not only wound infection but also respiratory trouble was much more frequent when the operation was protracted. After an hour and a half 25% of the patients suffer from one of these complications. No doubt chemotherapy will reduce wound infection enormously, but hitherto it has had little effect on the incidence of postoperative lung complications in our own abdominal cases. The average case requiring bilateral nylon darn is usually completed in under an hour.

Though some surgeons may object to a nylon darn in uncomplicated hernia, in strangulated cases the repair of the defect by a nylon darn must be given special consideration in view of our findings. With the attendant high risk of sepsis in strangulated hernia, few surgeons, as a routine procedure, have performed with impunity a repair with thread, silk, or filigree. Fascia also is usually out of the question, for the patients are in a weakened state and react badly to the lengthy procedure of a fascial darn; moreover, as Williamson (1941) indicated, sepsis is liable to nullify the effects of a fascial darn. We have hitherto used a nylon darn in 18 strangulated cases, 5 of which required resection of bowel, and sepsis resulted in only 1 case. Further, 18 strangulated femoral herniæ have been repaired with sutures of nylon without sepsis. In all strangulated cases a sound repair has been obtained.

We have found nylon much easier to handle than other materials which might be used for a darn, such as stainless-steel wire and tantalum.

Since April 30, 1947, an additional 239 inguinal darns, direct, indirect, and strangulated, have been performed by ourselves and our assistants; sepsis occurred 5 times but all cases healed without extrusion of the darn. No inguinal case darned with nylon has yet recurred.

SUMMARY

Nylon has been used as a darning material to repair various kinds of herniæ, particularly direct and indirect inguinal herniæ, both simple and strangulated. It has given general satisfaction, especially in strangulated herniæ.

We are indebted to Sir Heneage Ogilvie for his advice and helpful criticism. The illustrations are the work of Miss A. J. Arnott, to whom we owe our thanks.

INFECTION with *Leptospira canicola* is widespread among dogs, and the organisms are excreted in the urine for some months after recovery. Human cases of the disease were first recognised in Holland by Dhont et al. (1934), who isolated strains from 2 patients and from a number of dogs. Canicola fever in man has been reported from most European countries, North and South America, China and the Pacific Islands, but the total number is small. Minkenhof (1948) has collected from all over the world records of only 98 cases, nearly half of which were diagnosed in Holland.

In Britain one previous human case was investigated by Baber and Stuart (1946), but the source of infection was not traced, and Stuart (1938) found serological evidence of past infection in another instance. It may be of interest therefore to give in some detail the course of the disease in the present cases.

Case 1 (by L. J. M. L.).—An apprentice fitter and turner, aged 19, was admitted to hospital on Sept. 15, 1947, as a case of cerebrospinal meningitis. He had been taken ill suddenly, on Sept. 11, with frontal headache, fever, and sweating. Next day his eyes were red and the neck stiff. On the fifth day a pink blotchy rash appeared on the face and chest. The bowels had been confined 4 days and no drugs had been taken.

Previous Illnesses.—Measles and rubella.

Family History.—Nothing significant.

On Admission.—Fifth day of illness. Temperature 100·8°F, pulse-rate 68, respiration-rate 22 per min. The patient was a well-nourished young man, conscious, alert, and coöperative. The palpebral and bulbar conjunctivæ were intensely injected and red, with little discharge and pronounced photophobia. There was a pink discrete macular rash chiefly on the chest, abdomen, and back, and a little less on the face and extremities. The rash was morbilliform but lighter in colour than that of measles and not irritating. He had no cough, no Koplik's spots, and no redness or ulceration of the buccal mucosa. There was no enlargement of the lymph-glands or spleen and no jaundice. Clinical examination of heart, lungs, and abdomen revealed nothing abnormal. Blood-pressure 130/80 mm. Hg; urine, sp. gr. 1·020; no abnormality. There was no urethral discharge and no sore on the genitals. There was some stiffness of the neck on flexion but Kernig's sign was negative and he could kiss his knees. Cranial nerves, fundi, and ears were normal. There was no loss of power or sensation and all the reflexes were normal. Lumbar-puncture fluid clear and colourless with less than 4 cells per c.mm.: protein 30 mg. per 100 ml.; chlorides 690 mg. per 100 ml; and no organisms.

Subsequent Course.—On Sept. 19 (8th day) his temperature was 101·4°F, he was drowsy, his neck was more stiff, he could not kiss his knees, and Kernig's sign was positive. Lumbar puncture now gave a faintly opalescent spinal fluid with 200 cells per c.mm. (mononuclears 50%); protein 30 mg per 100 ml.; chlorides 680 mg. per 100 ml.; no organisms, and sterile on culture. White-cell count: 6800 per c.mm. (polymorphs 76·5%, eosinophils 0·5%, basophils 1%, monocytes 1%, and lymphocytes 21%). Blood-culture (twice), Widal test, Wassermann and Kahn tests, and Paul-Bunnell tests were all negative. X-ray films of the nasal sinuses showed no evidence of infection.

---

* The four cases described in this communication are recorded by three clinicians and the final serological diagnoses were made by the bacteriologist. The case-reports are the work of the individual physicians, each of whom is responsible for his own stated opinions only. It seemed advisable to publish all the records together.

On Sept. 20 (9th day) his temperature was normal and it remained normal afterwards. The rash faded rapidly after that date without leaving any staining of the skin. On Oct. 3 (22nd day) his eyes were normal, all traces of meningitic signs had disappeared, and no abnormal neurological signs could be detected. He was discharged home quite well on Oct. 20, the 39th day after the illness began.

A differential diagnosis had to be made between rubella, measles, erythema multiforme, Stevens-Johnson syndrome, and secondary syphilis. The possibility of some bacterial or viral meningitis had also to be considered. Against rubella was the late appearance of the rash, its larger elements, and the absence of enlargement of lymph-glands. Against measles was the colour of the rash and the absence of staining, the total absence of cough, and the lack of swelling of the eyelids and of discharge in the presence of such a severe conjunctivitis. The shape and distribution of the skin lesions and the absence of involvement of the buccal mucosa did not suggest either erythema multiforme or Stevens-Johnson syndrome. The rapid subsidence of the eruption and the negative serological tests excluded secondary syphilis. The rash bore no resemblance to any seen in meningococcal infections, and the negative blood-culture, the sterile cerebrospinal fluid, and the patient's rapid recovery were against cerebrospinal fever.

A diagnosis of "aseptic benign meningitis" of virus ætiology—e.g., poliomyelitis, choriomeningitis, &c.—was not acceptable as it did not account for two outstanding features, the severe conjunctivitis and the macular rash. The possibility of leptospiral meningitis was then thought of,† and by a series of agglutination tests of blood taken on the 24th, 50th, and 100th days after the onset a diagnosis of infection by *Leptospira canicola* was established. The details of the serological tests are given below.

The patient had kept a puppy, six months old, just before his illness, but so far as he knew the dog was healthy. Unfortunately this dog was accidentally killed before the patient's infection was diagnosed.

TABLE I—AGGLUTINATION OF *L. canicola* AND *L. icterohæmorrhagiæ* BY SERUM OF CASE 3 AT DIFFERENT INTERVALS AFTER ONSET OF DISEASE

Serum titre against	Days after onset				
	12	14	24	32	150
L. canicola ..	1/3000	1/10,000	1/10,000	1/10,000	1/300
L. icterohæmorrhagiæ ..	1/30	1/300	1/100	1/100	0

0 = No agglutination in dilution of 1/10.

(I wish to thank Dr. H. S. Banks, physician-superintendent, for permission to publish an account of this case, Dr. J. E. McCartney for the pathological reports, and my colleague Dr. Isenberg who kept the clinical notes.)

Case 2 (by T. S. M. N.).—A woman, aged 28, was admitted to hospital on Sept. 25, 1947. She had been quite well until 5 days before admission, since when she had suffered from increasing headache, vertigo, and vomiting. Small red spots, which disappeared after 24 hours, had been noticed on the right arm and on both legs.

On Admission.—Fifth day of illness. Temperature 101°F, pulse-rate 84, respiration-rate 20 per min. The patient was pale, her tongue was furred, there was well-marked neck-rigidity, and Kernig's sign was positive. The eyes, cranial nerves, and ears were normal. Lumbar puncture (3 hours after admission): fluid turbid; 1320 cells per c.mm. (lymphocytes 80%); total protein, 100 mg. per 100 ml., excess of globulin; chlorides 750 mg. per 100 ml.; no bacteria (including tubercle bacilli) seen in films; culture sterile.

Subsequent Course.—On Sept. 26 (6th day) her white-cell count was 8000 per c.mm. (polymorphs 44%, eosinophils 3%, basophils 2%, lymphocytes 46%, large mononuclears 5%).

The patient was treated with 60,000 units of penicillin 3-hourly for 5 days, and sulphadiazine to a total of 34 g. over 4 days. Her temperature settled in 36 hours after admission and her general condition rapidly improved.

On Sept. 29 (9th day) the left pupil was larger than the right, and there was left-sided ciliary injection. Neck rigidity had disappeared, and Kernig's sign was negative. Lumbar puncture: fluid slightly opalescent; 33 cells per c.mm.; total protein 40 mg. per 100 ml., globulin not in excess; no bacteria seen in films; culture sterile.

TABLE II—AGGLUTINATION OF *L. canicola* AND *L. icterohæmorrhagiæ* BY SERUM OF CASE 3 AFTER ABSORPTION

Titre against	Serum absorbed with		Unabsorbed
	L. canicola	*L. icterohæmorrhagiæ*	
L. canicola	0	1/3000	1/10,000
L. icterohæmorrhagiæ	0	0	1/300

0 = No agglutination in dilution of 1/10.

On Oct. 6 (16th day) the pyrexia recurred and persisted for 48 hours. The tip of the spleen was just palpable. On Oct. 8 (18th day) she insisted on taking her discharge from hospital because she was worried about her four children. She attended the medical outpatient department on Oct. 20 (30th day), when she felt well but showed right-sided ciliary injection and bilateral blurring of the edges of the optic discs was seen. Between the 40th and 90th days of her illness the patient reported to the outpatient department on three occasions, complaining of severe headache. Since then she has remained well.

The combination of acute aseptic meningitis and ciliary injection suggested a leptospiral infection (Buzzard and Wylie 1947), and a diagnosis of *L. canicola* infection was confirmed by the serological findings which are reported below.

Until very shortly before the illness began the patient had a puppy which had diarrhœa and she frequently cleared up its urine and fæces. She had disposed of the puppy before coming to hospital and could not trace it.

Case 3 (by J. M.S.).—A woman, aged 40, was admitted to hospital on Oct. 1, 1947, with the following history.

On Sept. 23 she had a headache and malaise and in the evening suffered from an attack of shivering. Next day, the symptoms were worse and there were aching pains in the limbs. The patient collapsed on getting out of bed, and her temperature was found to be 105°F when she was seen later in the day by her doctor. On the 3rd day meningitis was suspected and a course of sulphathiazole treatment begun. On the 4th day vomiting became troublesome, and a mistiness of vision developed in both eyes and lasted for 48 hours. The patient was unable to see objects directly ahead but could see things "out of the corner of her eyes" fairly clearly. On the 5th day spots, similar in appearance and distribution to erythema nodosum, appeared on both legs, but they cleared in about 2 days. By the 8th day it was evident that the condition was not responding to sulphonamides and the patient was sent to hospital for further investigation.

On Admission.—Ninth day of illness. The patient still complained of severe occipital headache and pain at the back of her neck. There were now no pains in the limbs and no further nausea or vomiting. Micturition was normal, but she was severely constipated. She looked ill and was flushed and

---

† I am indebted to Dr. E. T. Conybeare, of the Ministry of Health, for the suggestion in the summer of 1947 that some cases of lymphocytic meningitis might be due to leptospirosis.—L. J. M. L.

Such energies are foreign to chemical reactions, for these are concerned solely with orbital electrons and involve no disintegration of the atomic nucleus. Expressed in units similar to those used in nuclear reactions, the entire range of chemical reaction energies falls between 0 and 10 electron volts (Kamen 1947), a figure which contrasts with the beta-particle energy of the hydrogen isotope tritium, which, though classed as an emitter of low energy, achieves 0·015 million electron volts.

Some isotopes emit alpha particles as well as the foregoing; these are of large mass, low velocity, and great destructive power, but such isotopes are uncommon and infrequently used in biological studies.

Adequate information about the pathological potentialities of radioactive isotopes is lacking, especially about the late effects of isotope administration, though it is possible, in view of the large amounts of radioactive material which have already been administered to patients, that time will remedy this deficit. Meanwhile it is often necessary to draw conclusions from the better-known effects of radium emanations, which, though different in some ways from the emission of most isotopes, may be considered similar from the practical point of view. The main disturbances following undue exposure to radium or to X rays are skin effects, blood changes, genetic effects, sterility, and late neoplasia. A radioactive isotope can produce all these effects if it is present in large enough amounts and for a sufficient time.

SKIN EFFECTS

Epilation of the skin is observed commonly after undue exposure to radiations, and this effect may manifest itself upon the backs of the hands of those who handle radioactive substances; but a more serious consequence is a radiation necrosis, which appears after a latent interval and is slow to heal and extremely painful. A carcinoma is a not uncommon sequel. Certain of the rarer radioactive substances, such as plutonium, produce fibrosarcomas, even if the site of entrance is but a small cut in the finger. In animals an injection of 1 µg. of Pu^{239} is adequate to produce them, and bone sarcoma is a common occurrence after the introduction of fission products (Lisco et al. 1947).

As regards the commoner isotopes, skin tumours after beta burns from P^{32} have been noted by Raper (1947), who enclosed mice and rats within bakelite boxes containing radiophosphorus in their walls. In man, isotope burns are not uncommon, 5 millicuries of P^{32} being quite sufficient, or even a less amount if the skin is exposed to the active substance for a long time, as exemplified by the damage to terminal phalanges of those painting luminous instrument dials (Horner 1942).

The guiding star of the isotope worker is the law of inverse squares, and it is to be remembered that a specimen having a small total activity "measured across the bench" may give an enormous tissue dose underneath the finger-nail. This is of special importance to those concerned with the local application of isotopes for the treatment of skin diseases.

BLOOD CHANGES

Raper (1947) has remarked on the unchanged blood picture of the rabbit exposed to considerable amounts of beta radiation from P^{32}. It is evident that even in the case of gamma radiation the blood picture is an unreliable indicator of early damage (Lorenz et al. 1947), while Jacobson and Marks (1947) go so far as to suggest that any change should exclude a worker from further exposure.

As regards "neoplasias," Lorenz et al. (1947) have noted leukæmia and the production of carcinomas in animals not usually subject to them, and these with irradiations within the so-called tolerance range. In this connexion the raised incidence of leukæmia in those who handle radium or use X rays will be recalled. It is well to remember that, in all probability, radiation damage to the hæmatopoietic system, as to the skin, is not completely reparable (Stone 1947).

GENETIC EFFECTS

The possibility of genetic change as a result of ionising radiation has been discussed at a symposium held at the British Institute of Radiology (*Nature* 1946) and has been mentioned by McWhirter (1947) in connexion with the internal use of radioactive isotopes, by Van Roojen (1946) as a by-product of atomic warfare, and by Voegtlin (1941) in relation to clinical and laboratory personnel. Spear (1946) and Muller (1947) have provided full accounts of the genetic and other biological effects of penetrating radiations, and, although there is insufficient evidence on this important issue, Snell's (1941) observations certainly suggest that such might indeed occur, with possible evil effects on subsequent generations. As regards these effects, Newell (1941) says: "Even small doses of radiation administered to persons who may in the future have children are looked upon with extremely grave apprehension," and Henshaw (1945) has pointed out that radiation effects on genes and chromosomes occur without threshold.

STERILITY

Reduced sperm counts were observed after the atomic bombing of Hiroshima, and Platt (1947) has reported pathological changes in patients treated with P^{32}, with testicular and ovarian findings suggesting a distinct possibility of sterility, even though the doses used were only 0·1–2·5 millicuries two or three times a week. Whether such changes are reversible is uncertain, but current observations suggest, in mice, the recovery of the testis but not of the ovary. Lorenz et al. (1947) noted that total doses of 770–880r produced lasting sterility in female mice, regardless of the rate and intensity of administration, thus suggesting the possibility of cumulative damage.

EFFECTS OF INGESTION

The actions of radioactive materials taken into the body have certain special aspects. Many are familiar with the bronchial carcinomas of those who work in radioactive dusts, the bone sarcomas and aplastic anæmias of the old-time luminous watch-dial painters, and the terrible end of Dr. S. A. Von Sochocky (Martland 1929), who died with severe burns, hæmoptysis, hæmaturia, retinal hæmorrhages, and bronchopneumonia after exposure to radioactive materials in his laboratory. It may be noted, for comparison, that a lethal dose of tetanus toxin is about 220 µg., whereas 1 µg. of radium distributed throughout the body is sufficient to produce a fatal outcome, and even a tiny dust particle containing C^{14}, if inhaled, can give rise to a point dosage of radiation above the tolerance limit for tumour production. A resemblance to radium is shown by certain other radioactive substances, and Brues et al. (1947) have pointed out that Sr^{89} (half-life 55 days) is a most efficient producer of bone tumours, and that Ce^{144} causes liver damage as well as bone sarcomas. Y^{91} is almost unabsorbed from the gut, but it can produce several intestinal disorders. The tendency of the fission products to produce bone tumours depends mainly on their propensity for selective absorption in these structures (Hamilton 1947). Of the more common isotopes, there is no doubt that P^{32} can produce deleterious effects.

The clinician who proposes to administer a radioactive substance to a patient takes upon himself a grave responsibility, and such a project involves a consideration of the dose, the half-life of the element and emission energies, the manner of its body distribution—i.e., otal body (sodium) or local tissue concentration (iodine), he excretion-rate, and the extent of tissue dilution.

It is evident that, for many substances, adequate nformation is not available on all these points; and, s regards dosage, one has to admit that isotope standardisation is still somewhat unsatisfactory, and lisastrous consequences may follow inadvertent overdosage. Some estimation of the amount of radiation received is requisite and can be obtained with the help of the following formulæ:

$R = 60\ CE_{av}$, which deals with daily roentgen dose R, derived from an isotope with average tissue concentration C in millicuries per kg. of average particle energy E_{av}. For simple beta emitters $\frac{E\ max}{3} = E_{av}$. If there are gammas also, 20% must be added.

For a short-life isotope the total dose is more important d is given by the following:

$D = 1{\cdot}44\ RT$, when D = dose in R; R = initial daily se from the first formula; and T is the half-life in days.

For details Marinelli (1942) or Evans (1947) should be onsulted. The upper tolerance limit varies between 01 and 0·1 roentgens a day, according to different uthorities, but in this connexion it must be admitted at it is difficult to ascribe a tolerance dose to such diation damage as late neoplasia, premature ageing, nd genetic change. Henshaw (1945) suggests that tolerance injury" would be a better term in these ases, pointing out that, though the individual is continually bombarded by earth and cosmic radiation at bout 0·001r a day, the range of radiation exposure ompatible with life is none the less narrow.

CONCLUSIONS

It is to be emphasised that, in human experimentation, here is no excuse for using an isotope technique when ome ordinary chemical procedure would suffice. If the roblem will not yield to a chemical approach, it is esirable before using a radioactive isotope to consider the possibilities offered by a stable isotope which can be readily detected and, with the exception of deuterium, can be administered ad lib. without biological effect. Radiophosphorus should not be used in the treatment of patients in the reproductive period of life, or who have an expectation of life of five years or more (*British Medical Journal* 1947).

Isotope work is totally unsuited to a general laboratory such as the clinical laboratory of a hospital. Unless special precautions are taken, the benches, sinks, and furniture can become heavily contaminated with radioactive materials; and, if elements of long half-life, such as Co^{60}, Sr^{89}, or Zn^{65}, are used, the accumulated radiation may soon reach a dangerous level. Excellent accounts of laboratory hazards and the means for reducing them have been given by Sullivan (1947) and in some textbooks on radium.

Finally, those intending to employ radioactive isotopes for clinical purposes should make contact with the isotope section of the Medical Research Council, where advice from experts is readily available.

NEONATAL GASTROCOLIC FISTULA

REPORT OF A CASE

N. K. PEIN
M.B. Witwatersrand
RESIDENT MEDICAL OFFICER, SOUTHAMPTON CHILDREN'S HOSPITAL

NEONATAL gastrocolic fistula being extremely rare, the following case is of interest.

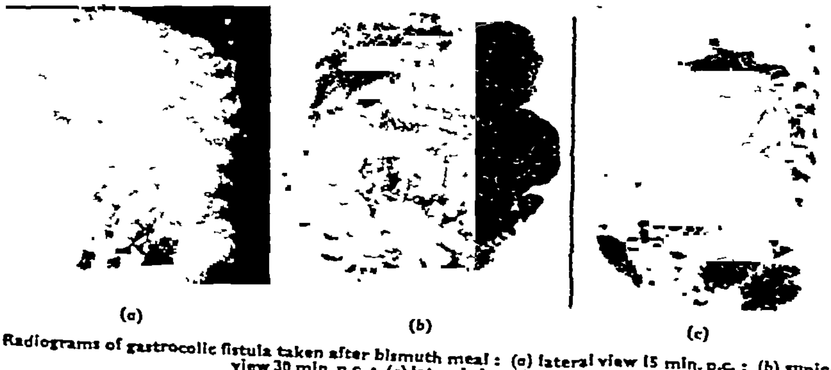
A male baby, aged 5 weeks, was admitted to the Southampton Children's Hospital because of difficulty with feeding and lack of progress.

The mother had been well during her pregnancy. The baby had been apparently healthy at birth though somewhat cyanotic on delivery and the usual methods of resuscitation had been applied.

During the first week or two the baby had been lethargic and had taken the breast poorly. Several brands of artificial milk were tried, but he continued to lose weight. Stools had become large, greenish, offensive, and slimy, and numbered about seven daily. Vomiting had increased, and the baby's condition had deteriorated sufficiently to merit admission to hospital.

On examination the baby weighed 7 lb., and, though normal in size, was obviously undernourished. His breath had an acid odour, and there was thrush in mouth and pharynx. Abdomen much distended and tympanitic; greenish slimy undigested food in rectum. Nothing else abnormal found.

Blood-count: red cells 3,150,000 per c.mm.; Hb 54%; white cells 10,400 per c.mm. (polymorphs 48%, lymphocytes 45%, monocytes 7%). Blood Wassermann reaction negative.



(a) (b) (c)

Radiograms of gastrocolic fistula taken after bismuth meal: (a) lateral view 15 min. p.c.; (b) supine view 30 min. p.c.; (c) lateral view 30 min. p.c.

Treatment was directed towards relieving dehydration and regulating feeds. Transfusions of citrated blood were given into scalp veins to combat anæmia.

Progress.—The baby put on ½ lb. in weight, which remained stationary for another ten days but then began to decrease because vomiting and diarrhœa, which had ceased on admission to hospital, began again. Vomit was highly acid, mustard-coloured, and rather offensive, and came up after each feed. Stools were at first normal in colour and consistence but, after a few days, began to resemble the vomit.

The vomit was now recognised as having a fæcal character; so gastrocolic fistula was tentatively diagnosed. This was confirmed by radiography after a bismuth meal. Radiograms taken at 15 min. and 30 min. in lateral and supine positions showed bismuth flowing directly from stomach into transverse colon (see figure).

Operation.—Next day laparatomy under local anæsthesia was performed by Mr. L. A. Richardson. Fistula between stomach and colon was easily found. It was about half an inch in diameter and connected greater curvature of stomach about its mid-point with transverse colon about 1 in. from splenic flexure.

Fistula appeared to be of inflammatory origin, since stomach easily peeled off colon, disclosing layers of œdematous tissue. Colon and stomach were closed separately, operation being rapidly completed.

Postoperative Course.—Penicillin and succinyl sulphathiazole were given, and small feeds at short intervals, but the baby died two days after operation.

Necropsy Findings.—Operative area free from infection: suture lines in stomach and colon healthy. Inside stomach an ulcer 3 mm. in diameter was found, which on section appeared to be a small chronic gastric ulcer. Microscopically mucosa showed ulcer and sinus with much subacute inflammation and granulation tissue.

COMMENT

The ætiology of the gastrocolic fistula is problematical. Any kind of developmental fistula seems embryologically improbable, whereas the inflammatory character of the tissues adjacent to the fistula strongly suggests a peptic ulcer which, starting in fœtal life, had perforated the adjacent colon.

I wish to thank Dr. K. E. Slaney for kind permission to publish this case, and Dr. G. Ormiston for his helpful criticism.

APPARENT ACUTE GLOMERULONEPHRITIS WITHOUT ALBUMINURIA

REPORT OF A CASE

JOHN CROFTON
M.D. Camb., M.R.C.P.
LECTURER IN MEDICINE, POSTGRADUATE MEDICAL SCHOOL OF LONDON

LESLIE TRUELOVE
B.M. Oxfd
LATE HOUSE-PHYSICIAN, HAMMERSMITH HOSPITAL

ALBUMINURIA is usually regarded as essential to a diagnosis of acute glomerulonephritis. In the following case, however, we felt justified in making this diagnosis in spite of the failure to detect any urinary abnormality apart from the doubtful presence of albuminuria on one occasion.

A girl, aged 16, employed as a pill-packer, was admitted to Hammersmith Hospital on Feb. 14, 1947. She had previously been healthy except for an attack of "eczema of the scalp" at the age of 7, and a similar attack, diagnosed as pediculosis capitis with secondary infection, in April, 1946.

Three weeks before admission she developed a dry cough and a slight sore throat. She felt ill and remained in bed for a week. She then returned to work, but the cough persisted. On Feb. 9 she had a severe frontal headache and noted that her eyes were puffy. Next day she complained of pain in the region of the lower sternum and of breathlessness on exertion. That night the pain and breathlessness were so severe that she could not lie down. On Feb. 11 she noted swelling of her face; she had 4 loose stools on Feb. 13; and on the 14th, the day of admission, her legs and ankles became swollen.

On admission her temperature was 99·8°F, pulse-rate 64 and respirations 28 per min., and blood-pressure 176/96 mm. Hg. She was pale and orthopnœic. There was well-marked puffiness of the face, a sacral pad of œdema, and gross pitting œdema of the ankles. The jugular venous pressure was level with the sternal angle. The liver was not palpable. The optic discs appeared normal. The fauces were a little reddened. The heart showed accentuation of the secon sound at the apex; occasional râles were heard at the bas of the lungs. There was no evidence of coarctation of th aorta.

Urine: sp. gr. 1·020, no albumin, no sugar; deposit contained a few epithelial cells, an occasional leucocyte, an numerous mobile bacilli, but no casts.

Progress.—The patient was treated in bed on a low-protei low-sodium diet, with fluids restricted to a litre a-day for th first week. Intramuscular penicillin, 30,000 units thre hourly, was given for the first three days. Diuresis bega within thirty-six hours of admission, and œdema disappeare by the sixth day in hospital. Her temperature reached 100° on the second evening and was thereafter normal. Her bloo pressure rose to 182/110 mm. Hg on the fourth day but ha fallen to 126/70 by the seventh. A small right pleural effusio confirmed radiologically, developed on the second day aft admission and disappeared in a few days. Transient systol cardiac murmurs appeared at the apex and in the second righ interspace as the blood-pressure fell.

The urine was examined at least once daily throughou Albumin was reported by a nurse in an early morning specime on the eleventh day; this specimen was unfortunately di carded, but another tested later the same morning showed n abnormality. Apart from this occasion, no abnormality wa detected throughout the patient's stay in hospital. She wa discharged on March 25 without symptoms or abnorm physical signs.

Investigations

Blood-urea: Feb. 17, 24 mg.; Feb. 21, 33 mg. per 100 m

Blood-proteins: Feb. 21, total 8·7 g., albumin 5·0 g globulin 3·7 g. per 100 ml.; March 5, total 7·7 g., albumin 4·2 g., globulin 3·5 g. per 100 ml.

Throat swab: Feb. 14, no hæmolytic streptococci found.

Blood-count: Feb. 15, red cells 4,100,000 per c.mm. Hb 69% (10·8 g. per 100 ml.); colour-index 0·84; whit cells 7000 per c.mm. (neutrophils 62%, eosinophils 1% lymphocytes 29%, monocytes 8%).

Blood Wassermann reaction and Kahn test negative.

Electrocardiogram: March 13, P–R interval 0·22 sec.; n other abnormality.

Antistreptolysin titre unfortunately could not be estimate owing to technical difficulties.

DISCUSSION

In spite of the normal urine, it was difficult to mak any diagnosis other than acute glomerulonephritis in an illness developing three weeks after an upper respiratory infection and characterised by fever, generalised œdema and hypertension, all of which disappeared within a few days. We have found no account of a similar case published in England or North America, though we have heard through colleagues of at least 3 cases in the British Isles. Further cases have been described on the Continent. Fenini (1872) mentioned 6 cases of postscarlatinal nephritis without albuminuria, 3 being confirmed at necropsy. Litten (1882) had a similar case, and Henoch (1899) recalled 6, in which the diagnosis was apparently confirmed at necropsy and some of which did develop albuminuria in the last few days of life; he gave a detailed account of one of these cases.

All of these cases were postscarlatinal, and in none of them, of course, is the blood-pressure recorded. Nonnenbruch (1916), in reporting a case of trench nephritis, seems to have been the first to describe hypertension, as well as œdema, occurring without albuminuria He mentioned 2 other cases in which albuminuria appeared only after several days. Topfer (1917) claimed that in many cases of trench nephritis œdema wa present without albuminuria, but since most of these occurred among Russian prisoners-of-war the condition may have been hunger œdema. Mayer (1922) reviewed the published cases up to that time and added 2 uncon vincing ones, neither of which developed a significant rise in blood-pressure. Kylin (1922) observed severa patients with a transient rise in blood-pressure but no abnormality in the urine; he suggested that these might be cryptic cases of acute glomerulonephritis but gave no further clinical details. Wickbom (1928) reported 3 cases, only 1 of which showed a raised blood-pressure; in 2 of them red cells were present in the urine in spite of the absence of albumin. He also examined his patients' urine daily during a hospital epidemic of staphylococcal sore throat and found a moderate number of red cells in 7 out of 52 cases from four to nine days after the acute infection. In 6 of these, casts of an unspecified type were also present, but in none was there albuminuria. He boldly interpreted these findings as indicating minimal acute glomerulonephritis.

In Chile Alessandri and Roeschmann (1942) have described, among 248 cases of acute nephritis, 6 in which urinary signs were either absent or minimal and transient; 5 of these occurred from seven to ten days after tonsillitis or an acute skin infection. Definite hypertension was noted in 4 of the 6, and the blood-pressure reached the upper limits of normal in the remaining 2. One patient died from pulmonary œdema 10 minutes after an intravenous injection of ether, given to measure the circulation-time. Clinically, there had been well-marked peripheral œdema, and the blood-pressure rose to 160/110 mm. Hg, though no abnormality was found in the urine. At necropsy an intense acute glomerulonephritis was found.

We will not attempt to discuss the theoretical implication of these cases. None of the necropsy accounts describes the histology of the kidneys in detail, and there is no record of serial sections having been made. Without further data, any explanation would be speculative. It seems clear that an illness resembling acute glomerulonephritis but lacking urinary abnormality can occur. More records and fuller investigation of this illness are desirable.

SUMMARY

A girl of 16 developed transient hypertension and œdema consistent with a diagnosis of acute glomerular nephritis but no urinary abnormality was found except for doubtful albuminuria on one occasion.

The published examples of acute glomerulonephritis without albuminuria are briefly reviewed.

> "... In brief, I hold that from the very beginning of human evolution the conduct of every local group was regulated by two codes of morality, distinguished by Herbert Spencer as the 'code of amity' and the 'code of enmity.' There were thus exposed to 'natural selection' two opposing aspects of man's mental nature.... How the neural basis of such qualities, both good and bad, came into existence during the progressive development of the human brain, we do not know, but it is clear that the chances of survival of a struggling, evolving group would be strengthened by both sets of qualities. These two sets of opposite qualities must be balanced to secure continuous, progressive evolutionary changes.... It will thus be seen that I look on the duality of human nature as an essential part of the machinery of human evolution. It is the corner-stone of my mosaic edifice. Human nature is both a product and a process. It has been built up as a product of man's evolution, but it has been developed so as to serve in the process of evolutionary change."—Sir ARTHUR KEITH, F.R.S., in a *New Theory of Human Evolution*, London, 1948.

EPIDEMIC OF BULLOUS ERYTHEMA ON LEGS DUE TO BED-BUGS

J. KINNEAR
M.D. St. And., M.R.C.P.E.
LECTURER IN DISEASES OF THE SKIN, UNIVERSITY OF ST. ANDREWS; PHYSICIAN FOR DISEASES OF THE SKIN, DUNDEE ROYAL INFIRMARY

IN June, 1947, a woman presented herself complaining of recurring blisters on her legs. The lesions had appeared at intervals for some months. A band of erythema was found across the back of both calves just above their maximal circumference. This erythematous zone was studded with bullæ varying in size up to that of a pigeon's egg. The lesions were considered to be most likely due to insect bites, but no history of duties at home or at work likely to expose the calves to attack in this manner was obtained. The question of a chemical burn was gone into, but this appeared very unlikely, and there had been no marks on the stockings. There was no possibility of a dermatitis striata bullosa pratensis.

A few days later a second patient appeared with exactly similar lesions—a zone of erythema studded with bullæ across the back of both calves at about the same level from the ground as in the first case. This patient was, however, more observant than the first; she said this was not the first attack she had had, and that the blisters always appeared a few hours after she had been in a tram-car on a certain route.

Within a fortnight some half-dozen further cases were seen, all exactly similar and all with a history of using the same tram route. All were women. A local practitioner telephoned to ask if I knew about the epidemic of blisters on ladies' calves, since he had had several cases. I told him to find out if his patients used this tram route, and he informed me later that they all did. News of further cases was also obtained from medical and non-medical sources, but the total number of women affected is not ascertainable.

Meantime the medical officer of health had been informed and the opinion given that a crawling insect was most likely to blame, not a "jumper" or a "flier," and that the trams on this route appeared to contain the culprits. At his request I inspected a tram-car similar to those used on this route and found that the seats on the lower deck (which was the one used by all the patients) consisted of two parallel leather-covered cushions running the length of the interior of the car. Each seat was kept in place by a vertical slat of wood running in front of the cushion. The lower edge of this slat of wood appeared to be the same height from the floor as the lesions, and, on sitting down and putting their feet as far back as possible, passengers would bring the calves of their legs into contact with the lower edge of the wood.

Representatives of the sanitary department thereupon inspected all the trams using the affected route. They were found to be free from infestation except for one car. In this vehicle the lower edges of the slats of wood were grooved, and these grooves were the habitat of numerous bed-bugs which evidently reversed their normal mode of life, lying hidden by night when the tram was in the garage and by day sitting in a row along the edge of the wood extracting nourishment from the legs of unsuspecting lady passengers. Men were never affected, their stouter nether garments providing sufficient protection.

The tram was disinfested, the grooves were planed out to prevent a recurrence, and the epidemic came to an abrupt stop. The interesting clinical point was the severity of the reaction to bed-bug bites. All cases seen and reported were frankly bullous.

Medical Societies

GENETICAL SOCIETY OF GREAT BRITAIN AND BRITISH EMPIRE CANCER CAMPAIGN

Genetics of Cancer

THESE two bodies held a joint symposium in London on June 24 and 25. On the first day the chair was taken by Mr. E. B. FORD, D.SC., F.R.S. and Mr. A. W. GREENWOOD, D.SC., and on the second by Prof. A. HADDOW, M.D. and Dr. CUTHBERT DUKES.

INHERITANCE OF CANCER IN ANIMALS

Dr. W. E. HESTON (Bethesda, U.S.A.) gave an account of work done at the National Cancer Institute showing the influence of hereditary factors on the production and transmission of the milk agent. This hereditary influence is shown by experiments on the offspring of matings between high and low cancer lines, whose children could be made to contain a variable quantity of high or low cancer nuclear material depending on whether they arose from back-crosses to the grand-parental strain with a high or low tumour incidence. Further experiments have been done using mice of a high cancer strain which had been deprived of the milk agent. These indicated that the milk factor accelerates genetic processes underlying tumour growth but is not active by itself.

Dr. R. KORTEWEG (Amsterdam), dealing with the influence of œstrogenic substances on tumour susceptibility, described experiments which have shown that the amount of hormone required to produce œstrus in spayed females of a high cancer strain is much higher than in low cancer strains. Excessive quantities of œstrone and possibly progesterone seem to be required in high cancer strains to produce physiological effects. Quantitative estimates of the relative sensitivity to œstrogens can be obtained by using the response of the mammary gland to find the least dose causing a physiological effect. Experiments have been confined to mice of the C57 and dba strains, the former having a low incidence of spontaneous tumours and the latter a high one. Males of the C57 strain have been shown to have a higher resistance to œstrone than females—an apparently contradictory finding since their incidence of mammary tumours is very low. This is apparently due to the antagonistic influence of male hormone. Dr. Korteweg suggested that the incidence of mammary tumours in high cancer lines is partly due to their excessive secretion of œstrogens, and consequently increased stimulation of the mammary gland.

Dr. L. DMOCHOWSKI (Leeds) showed that there are hereditary differences in the production of the milk agent. The differences in production could be demonstrated by an experiment in which it was shown that as mice grow older larger quantities of milk agent are required to initiate the development of mammary tumours. The amount of milk agent required in this experiment was found to vary according to the strain from which the extract was prepared, larger amounts being required from moderately high tumour strains than from very high tumour strains. Other experiments have indicated that there is a variation from strain to strain in the efficacy of sex hormones as factors in the causation of cancer.

Dr. P. A. GORER (London) outlined the history of tumour-transplantation studies. It was shown many years ago that the transplantability of a tumour is determined by complexes of dominant genes. Since then some of these genes have been found to determine the production of antigens which can be demonstrated serologically. Dr. Gorer suggested the term histo-compatibility antigen to describe these antigens. They can be found in all tissues, though it is easiest to work with red cells. Recent work has shown that the gene determining the production of one of the known antigens in mice is located on the same chromosome as the gene for Fused, an anomaly of the tail. The apparently high mutation-rate of the genes for histo-compatibility frequently makes transplanting between different sublines of the same pure line impossible. A high degree of polymorphism in relation to antigens may be desirable from an evolutionary point of view owing to the danger of fœtal/maternal incompatibility. The more antigens that a mother carries, the less likely is she to kill the fœtuses produced in mating at random with a variety of males. Such polymorphism has been found in some studies on the histo-compatibility antigens of wild mice. In some cases Dr. Gorer has found that a transplanted tumour may grow even in an antigenically incompatible host. This appears to be because in some cases the presence of a tumour depresses the antibody-producing powers of the host, a fact which is of some clinical interest.—During the discussion Dr. STRONG questioned the reality of the high mutation-rate suggested by Dr. Gorer. He has not noticed the same effect in his own mice and suggested that some of it can be accounted for by inadequate records or contamination in the breeding colony.

Dr. G. HOGREFFE (Copenhagen) described experiments on the genetics of leukæmia. The Aka strain of mice have an extremely high spontaneous incidence of this disease. When this line is out-crossed to another with a negligible incidence it is found that the frequency of leukæmia in the F_2 and back-cross experiments can be explained on the hypothesis that the disease is determined by the segregation of a single Mendelian factor. The results are complicated by the fact that in hybrids the age of incidence is greatly increased over that in the original Aka mice. Subsequent experiments on the transplantability of the leukæmia have shown that this process is far more complex in its determination than is the hereditary transmission of the disease.

Dr. C. C. SPICER (London) gave an account of a statistical approach to the problem of assessing the tumour susceptibility of pure lines. The simple percentage of tumour deaths is not adequate for this purpose as it is liable to be greatly altered by differences in the non-tumour death-rate, though the true tumour-susceptibility is unaltered. Application of this method to some existing data has given results diametrically opposed to those which would be deduced simply from the percentage of cancer deaths.—In the discussion Prof. J. B. S. HALDANE, F.R.S., who initiated the work, emphasised that the method can only be used on homogeneous material. Sharply heterogeneous data, such as that arising in an F_2 generation, cannot be treated by the same technique.

VIRUS- AND CARCINOGEN-INDUCED MUTATIONS

Dr. L. C. STRONG (Yale) gave a historical summary of work bearing on the possibility that cancer arises as a somatic or germinal mutation. In this connexion he defined mutation as the occurrence of an inheritable novelty passed on in all subsequent cell divisions. Germinal mutations are well known and the occurrence of somatic mutations has also been noted—for instance, in plants where some branches may show a different genetic structure from others on the same plant. In one case two tumours growing in the same mouse were found to have genes determining their transplantability although they were histologically identical. In recent years Dr. Strong has produced mutations in mice with methylcholanthrene by founding a line of animals selected for resistance to tumour formation at the site of injection of the carcinogen. A great variety of tumours have been produced by this method, including stomach and breast cancers histologically very similar to those in man. These tumours are inherited and appear to be due to germinal mutations. The sex-incidence of gastric cancer is similar to that in human beings. Somatic mutations as well as disturbances of growth and development have been produced by methylcholanthrene. This substance does not act purely as a carcinogen but apparently as a mutagen also. Dr. Strong mentioned the different effects on the nucleus that carcinogenic agents can have—for example, X rays and the nitrogen mustards produce chromosome breaks, whereas the classical carcinogens as a rule do not do this.

Dr. N. DEMEREC (Washington, U.S.A.) described his experiments on the production of mutations in *Drosophila melanogaster* by carcinogens. The technical difficulties in administering the carcinogens have been overcome by using aerosols of solutions containing the substance under test. A semi-automatic experimental technique has been devised by which controlled dosages can be given over a long period. The experimental results have shown that not all carcinogens can cause mutations since some quite powerful ones have not increased the mutation-rate. An interesting discovery arising from the work is that the mutation-rate can be controlled by a gene.—Dr. C. AUERBACH in the discussion suggested that the gene controls penetration of the carcinogen rather than the actual mutation-rate, but Dr. Demerec replied that experiments have indicated that this is not the case. Dr. Demerec remarked that if cancer is due to somatic or germinal mutation there seems to be little possibility of its prevention or control.

Mr. C. D. DARLINGTON, D.SC., F.R.S. (London) suggested that a continuous gradation exists in the hereditary mechanism from the transmission of plastid, which has apparently always been part of the cytoplasm, through the killer factor discovered by Sonneborn in paramecium, to viruses such as those causing Shope papilloma or contagious warts, which are believed to arise outside the cell and are regarded as infective organisms. The case of killer represents an intermediate stage, since it can be passed from one organism to the other in prolonged copulation, though this is not usual and it is normally passed on in cell division as a cytoplasmic inclusion. The killer factor has also been shown to be under genetic control.—In the discussion Dr. DEMEREC said that recent work has suggested that the killer factor is a parasite rather than a virus or a plasmagene.

Prof. P. B. MEDAWAR, D.SC., (Birmingham) gave an account of work which has shown that cells tend to breed true to type. For instance, the typical behaviour of cells from the sole of the foot is carried on when they were transplanted to the chest wall, and similar results have been obtained with claws and with cornea. He described the infective transformation of pigment cells in the guinea-pig. These are dendritic cells, some of which contain melanin while some do not. When a dendrite of a pigmented cell makes contact with a non-pigmented cell of the same species, then this cell becomes able to produce melanin and hence becomes pigmented.—In the discussion Dr. GEORGIANA BONSER suggested that the appearance of satellite melanomata may be accounted for in this way, and also that amelanotic melanomata may arise because the rate of growth of cells outstrips the rate of the infective process of pigmentation.

Prof. A. HADDOW (London) reviewed the work bearing on the relation of carcinogens and virus investigations of the origin of cancer. He contrasted the two kinds of agent. The carcinogens are of many different kinds but are usually of low molecular weight, not very specific in their effects, and not necessary to continued growth once a tumour has been induced. Viruses, on the other hand, are complex proteinoid substances very highly specific in their effects and necessary to continued growth of the tumour. The link between these two fundamentally different agents may be found in the influence of the carcinogen on some pre-existing cytoplasmic body analogous to a virus, either directly or through the nucleus.

Dr. J. G. CARR (London) described his experiments on the production of mutations in mice by carcinogens. He has used the descendants of a cross between members of an inbred high-tumour line and a stock of loosely inbred laboratory mice. The number of mutations observed has greatly exceeded what would be expected from spontaneous mutation.—Dr. E. B. FORD pointed out in the discussion that no controls were used. Dr. Carr suggested that there is some specificity in the action of carcinogens as mutagens, some loci being more mutable than others. Under these circumstances the offspring of parents exposed to the same carcinogen in industry may be expected to be carrying similar mutant genes, so that intermarriage among the children of similarly occupied parents may lead to some of the ill effects of inbreeding among relatives. This point was questioned by Professor HALDANE on statistical grounds and also by Dr. DEMEREC, who has found no specificity in the mutagenic action of carcinogens.

Prof. R. D. PASSEY (Leeds) described his electron microscope studies on the milk factor for tumour induction in mice. This work is still incomplete because only temporary access to the electron microscope has been possible. Once the technical problem of obtaining satisfactory defatted specimens of milk was solved, particles of fairly constant size (about 200–300 Å) were demonstrated in the milk of mice from high-tumour lines. Similar particles were absent or very scarce in the milk of mice from low-tumour lines. Further work is in progress to determine more precisely whether these particles are identical with the milk factor. At present it is not possible to assert this or even that the particles are viruses.

Dr. A. W. GREENWOOD (Edinburgh) discussed some work on the inheritance of susceptibility to the Rous sarcoma in fowls. This showed that both susceptibility and resistance to the tumour can be inherited, though in neither case can the heredity be explained on a simple Mendelian hypothesis. Attempts to develop a susceptible line of animals were discontinued owing to the war, but a resistant line has been successfully established by selection.

Dr. R. G. GOTTSCHALK (Liège) dealt with the relative susceptibility to carcinogens of adult and embryonic tissues. He pointed out that many writers have suggested that the embryonic state implies a special liability to cancer. His experiments have shown that, as judged by growth-rate of induced tumours and histological criteria, there is no difference in the liability of adult or embryo epidermis, though both are more susceptible than connective tissue.

INHERITANCE OF CANCER IN MAN

Prof. TAGE KEMP (Copenhagen) spoke of the work of the University Institute of Human Genetics at Copenhagen. Two major studies have been produced, one by Jacobsen on breast cancer and one by Videbaek on leukæmia. Jacobsen investigated the family history of 200 patients with breast cancer, and of 200 controls of the same age and class. He found that there is a hereditary disposition to breast cancer, possibly accompanied by a general susceptibility to all cancer. He also found that people with a family history of breast cancer tend to develop cancer at an earlier age than those who have no such history. Videbaek showed that there is no clear-cut hereditary predisposition to leukæmia although there is an excess of cancer over expectation in the families of leukæmic patients.

Mr. P. C. KOLLER, D.SC. (London) described two cases of xeroderma pigmentosum, a disease of the skin in which cancer sometimes develops. The inheritance of this disease has been explained by Haldane on the basis of partial sex-linkage, though the pedigrees shown by Dr. Koller did not support this suggestion very strongly. —In the discussion Professor HALDANE pointed out that Dr. Koller's two cases were not sufficient evidence to prove or disprove the partial sex-linkage of xeroderma.

Dr. T. BUSK (Copenhagen) gave an account of the studies carried out by the Danish Cancer Registry on cancer in twins. These have shown no excess of cancer in the other members of pairs of twins when one is suffering from cancer. This is true of both monozygotic and dizygotic twins. There is however a strongly marked correlation in the site of localisation of cancer, when it does occur.

Prof. D. W. SMITHERS, M.D. (London) has collected family histories of a large number of cases of breast cancer. They show a very strong familial tendency to breast cancer, though in distinction to the findings of the Danish workers he has found no signs that people with a family history of breast cancer tend to develop it younger than those without a family history.

Prof. L. S. PENROSE (London) has been collecting family histories of breast-cancer patients admitted to University College Hospital. The problem of a control group has been solved by using the Registrar-General's statistics, from which it is possible to calculate an expected proportion of breast cancer and cancer deaths among relatives dying at all ages and at most periods of the immediate past. In this way the expected number of cancer deaths and cases of breast cancer can be calculated for the relatives and compared with the observed figures. This work has shown that there is not an excessive amount of cancer as a whole among the relatives of breast-cancer patients, though there is a considerable excess of breast cancer among their mothers and sisters. There is no indication that the relatives of breast-cancer victims themselves develop the disease at younger ages. A secondary investigation has been made to discover whether anything analogous to the milk factor of mice can be found in man, by comparing the incidence of cancer in breast-fed and non-breast-fed children. No significant excess among the breast-fed has been found.—In the discussion Professor SMITHERS remarked on the extreme practical difficulty of obtaining reliable information as to whether a patient was breast-fed or not; almost all were breast-fed for at least a short time.—Professor PASSEY mentioned an investigation into the inheritance of breast cancer now in progress at Leeds; the work is still incomplete but the results differ from those of Professor Penrose in some respects.

Reviews of Books

Hallmarks of Mankind

FREDERICK WOOD JONES, D.SC., M.B., F.R.C.S., F.R.S., Sir William Collins professor of human and comparative anatomy, Royal College of Surgeons of England. London: Baillière. 1948. Pp. 86. *10s. 6d.*

ZOOLOGICALLY, it has for many years been generally accepted that man is one of the higher primates and that, on the usual morphological criteria employed for assessing taxonomic affinities, his closest relationships are evidently with the anthropoid apes. Yet it is obvious that in a number of anatomical features (such as the complexity of the brain, the form and disposition of the teeth, the construction of the foot, and the proportions of the limbs) man contrasts rather strongly with the apes. Prof. Wood Jones makes an interesting attempt to ascertain just how far some of these distinctively human features are really fundamental and how far they may be taken to indicate a relatively long independence of the human line of evolution. He lists a series of characters which from time to time have been advanced as distinctive of the human family, and emphasises their possible significance as indirect evidence of human phylogenesis. It will be apparent to the reader, however, that many of these features are by no means as distinctive of man as some authorities have supposed. For example, he points out that the sphenoparietal contact of the human skull, though very rare in the gorilla and chimpanzee, is the normal condition in the Asiatic apes and many types of monkeys. Multiple pyramids in the kidney are also to be found in the gorilla and chimpanzee as well as in man. The human pattern of origin of the large arteries from the aortic arch is also found in 90% of gorillas. Although this type of evidence in itself is thus bound to be inconclusive (for the details of human evolution will only be finally established by the fossil record), nevertheless it provides a broad basis for speculative inquiry and at least indicates possibilities or probabilities.

As usual, Prof. Wood Jones writes in an attractive and animated style, and his trenchant criticisms of some views which are now fairly widely accepted make lively reading. But in developing some of his arguments for the anatomical uniqueness of man he shows a tendency, by quoting isolated sentences out of their proper context, to caricature the opinions of his fellow anatomists. They will find themselves in good company, however, for both Charles Darwin and T. H. Huxley are vigorously censured for their mistaken ideas.

The Postnatal Development of the Human Cerebral Cortex

Vol. III. The Cortex of the Three-month Infant. J. LEROY CONEL, professor of anatomy, Boston University. Cambridge, Mass.: Harvard University Press. London: Oxford University Press. 1947. Pp. 158. 70*s.*

THE first two volumes, published in 1939 and 1941, described the development of the infant's cortex at birth and at one month. Now, at three months, the infant is just at the end of the inhibitory phase of the grasp reflex; he can converge his eyes on stationary and moving objects, and can make purposeful movements of the arms. Control of function is just beginning in the hands. All the histological criteria used in the analysis of the cytology of the cortex in this study agree in indicating that the region of the brain, FAγ, controlling muscular function in the upper trunk, arm, and forearm, is more advanced than elsewhere. The visual cortex, too, is sufficiently developed to suggest that some cortical vision is possible. Function in the acoustic area of the cortex may also be beginning, but is evidently slight according to histological criteria.

Histologists will be reassured to find that the Nissl bodies and neurofibrils are vindicated afresh as significant cytoplasmic furniture, and not artefacts. Along with other evidence of approaching maturity their evolution is traced by Conel from the earliest stages in different parts of the cortex, and they reach their highest point of development in this age-period in the motor area FAγ. The study is based on a standardised investigation of six normal brains, the technique and presentation conforming with those of the earlier age-groups. The plates again call for special commendation, and it is a pleasure to note that Miss Etta Piotti is still producing beautiful drawings of the neurones from Cox-Golgi preparations.

The Pathology of Nutritional Disease

RICHARD H. FOLLIS, Jr., M.D., associate professor of pathology, Duke University, Durham, North Carolina. Oxford: *Blackwell Scientific Publications.* 1948. Pp. 291 35*s.*

IN Professor Follis's own words, this book was written "to gather together the available information which deals with the physiological and morphological changes, occurring naturally or produced experimentally, which accompany deficiencies of one or more of the 40-odd nutrients now known to be essential." In a way he has succeeded in his task, for he has produced a fair-sized book with nearly 800 references. All the same, it is remarkable how little the histological and morphological changes seem to have been studied. Over and over again he has to record the absence of any work on a subject, and if the book merely draws attention to our ignorance it will have served a useful purpose. It contains chapters on the inorganic elements, essential amino-acids, fat-soluble and water-soluble vitamins, and the essential fatty acids, and it may be recommended to anyone wishing to look up the effect of a deficiency of any of these on the mammalia (he has excluded birds, bacteria, and invertebrates from his investigations). Unfortunately, however, the book is an uninspired production, with some curious lacunæ. Nothing is said, for example, about calories; though these are surely as important as inositol. Rather too much prominence is given to the writings of investigators with whom the author has collaborated, and there are very few references to the German, French, Italian, Swiss, Dutch, or Spanish work: readers must not expect a review of the international literature. But the book is well printed and there are over 70 beautifully reproduced photographs and photomicrographs. The sections on vitamins A, D, and C are particularly well illustrated.

La radiothérapie anti-inflammatoire

JEAN HUGUET, electro-radiologiste des hôpitaux de Marseille. Paris: Doin. 1947. Pp. 200. Fr. 440.

Dr. Huguet divides his account of the use of radiotherapy for the treatment of inflammatory diseases into three parts—a first period during which a tentative approach produced some good results but also some disasters, a second period during which the scientific basis was sound and a third the contemporary period of accurate dosage and physiopathological study. The conditions for which radiotherapy may be beneficial are described at length, and it is interesting to see how many and how varied are the lesions which have responded to different methods of treatment. The last two chapters are the most important; here the *mode of action of irradiation* is discussed and it is concluded that small doses act on the sensitive lymphoid and reticulo-endothelial hæmopoietic tissues; that the threshold of sensitivity is very low; and that the margin of safe dosage is very narrow before the point is reached where increased dosage does harm. Dose must, therefore, be low; and the more acute the condition the lower the dose. Treatment should not be repeated within 48 hours; and, if it is continued, doses should be increased together with the interval between treatments.

THE LANCET

LONDON: SATURDAY, JULY 10, 1948

Gamma-globulin in Measles

ANTIBODIES, as has long been known, reside mostly in the globulin fraction of the blood. Modern methods of fractionating the plasma proteins, as by electrophoresis and ultracentrifugation, have shown that the antibody is concentrated particularly in the gamma-globulin which constitutes about 11% of the total protein. When, early in the war, E. J. COHN and his colleagues at Harvard undertook the large-scale fractionation of human plasma by alcohol precipitation in the cold, with the primary object of supplying albumin for combating shock, they naturally used the same methods to separate the other protein moieties like fibrinogen and the globulins. Eventually, a viscous substance called fraction II, containing about 16% protein as practically pure gamma-globulin and with the natural antibodies concentrated 20- to 30-fold, was submitted to clinical trial. Whole blood, normal adult serum, and convalescent serum have all been used with varying success in the prevention or attenuation of measles, and the new gamma-globulin was therefore first tried in this infection. The results were astonishingly good; not only was the disease prevented or attenuated by small doses given early in the incubation period, but it was even claimed that the rash could be aborted when larger doses were given in the prodromal stage of infection.

The method of fractionation elaborated by the Harvard workers, involving such variables as pH, salt concentration, protein concentration, and the use of alcoholic solvents at a temperature range of 0 to − 10°C, could not readily be used extensively in Britain during the war. When, therefore, a gift of a litre of gamma-globulin was received from America in 1943, a small working party under the chairmanship of Sir PERCIVAL HARTLEY was set up to organise carefully controlled trials with the precious material. Their results are reported at the front of this issue. It was known from earlier experience, particularly in the London County Council fever service, that convalescent measles serum would protect a high proportion of contact children, aged 6 months to 5 years, if given in doses of 5–10 ml. within five to six days of exposure to measles; so this first batch of gamma-globulin was used in a comparative trial with convalescent measles serum on groups of susceptible children intimately exposed to infection in hospital, in day or residential nurseries, or in their own homes. The results in 139 children given gamma-globulin and a comparable group of 136 children given convalescent serum showed that the concentrated globulin was about twice as potent as the convalescent serum. Thus, in the most susceptible age-group of children aged 1–4 years, only 2 out of 28 given 2·5–3·5 ml. of globulin developed (mild) measles, compared with 7 out of 33 children given 5 ml. or more of convalescent serum. In contrast with earlier experience with placental globulins, there were no local or systemic reactions although the viscous solution had to be injected with a needle of fairly wide bore.

With the demonstration that gamma-globulin was both safe and effective, subsequent trials with fresh supplies received from America were devised to assay appropriate dosage for prevention or attenuation, to compare the potency of different batches, and to assess the keeping qualities of the antibody in liquid solution. When a dose of 0·1 ml. per lb. body-weight was used, a protection-rate of 92·6% was obtained from the sum of 13 different batches of globulins; 4 of the 5 unprotected children in this group developed mild measles. While the figures are too small to allow comparison of the potencies of different batches, there was at least one batch of low-potency globulin (omitted from the analysis above) which protected only 16 out of 28 children in the standard dosage of 0·1 ml. per lb. body-weight. Whatever was the cause of this deficiency, it seems unlikely, in a highly urbanised community where 80–90% of children develop measles, that concentrated globulin from pools of adult serum will vary much in their content of measles antibody. When attenuation rather than protection is desired, the American workers have recommended a quarter of the protecting dose, but the present study and experience with convalescent serum suggest that about half the standard dose should be used. Potency seemed to be maintained fairly well in the liquid preparation kept in cold storage for two years or more, though it should be noted that in the highly susceptible age-group of 1–4 years, 22 out of 110 children given "protective" doses of the outdated globulin developed measles. It would be wise, therefore, to freeze-dry batches of globulin that may have to be kept for some time before use.

Measles is not the killing disease it was even as late as twenty years ago, but it may still be a serious infection in young children and lead to crippling complications like otitis media and bronchopneumonia. Most doctors would therefore prefer to abort or attenuate the attack in susceptible children of 6 months to 3 years of age known to be exposed to infection. The supply of convalescent serum is always very limited; normal adult serum may modify but not usually prevent an attack unless given in large doses, and there is the small risk of homologous serum hepatitis. Concentrated globulin in amounts of 2–3 ml. will either give temporary protection or will so modify the attack that the risk to the child is minimal. And there has been no recorded instance of homologous serum hepatitis after many thousand injections of gamma-globulin. The main problem facing us is the large-scale supply of this commodity. The raw material will probably be obtainable in sufficient amount through the National Blood Transfusion Service. A method of concentrating the antibody-containing globulins, using precipitation with ether instead of alcohol, has been developed by

KEKWICK and his colleagues [1] at the Lister Institute, and already experimental batches of this globulin are being tested in controlled clinical trials with encouraging results. Meanwhile, until supplies become more generally available, normal adult serum, which is distributed by the Public Health Laboratory Service, may be used in doses of 5–10 ml. to modify the attack in young children.

There are other uses for gamma-globulin. It has already proved effective in the prophylaxis of infective hepatitis, and has even had some success against upper respiratory infections.[2] Like other preparations, it has failed to abort the paralytic stage of poliomyelitis and has given negative results in the control of chicken pox and mumps. Here it may be necessary to prepare a concentrated globulin from pools of convalescent serum; in one study [3] such a globulin apparently reduced the incidence of orchitis when given in doses of 20 ml. after the onset of mumps in young adults. We do not yet know whether it will protect the pregnant woman against rubella; but we can fairly hope that this substance, originally almost a waste product, will prove an effective new weapon against the still intractable virus infections.

A Tax on Knowledge

FROM time to time attention is drawn to the discouraging attitude of our income-tax law towards such professional expenses as the purchase of textbooks and scientific journals and subscriptions to societies. A correspondent serving in the Forces complains that no rebate is allowed him in his efforts to use these means of keeping abreast of current medical knowledge on a fixed salary. He suggests that a medical man in the Services is in this respect denied privileges which civilian doctors enjoy. But subject to the mysterious distinctions discoverable in the expense rules under schedules D and E, it does not appear that civilians obtain much greater advantage from the Inland Revenue than doctors serving in the Navy, Army, or Air Force.

The material passage for the latter seems to be found in schedule E, which charges tax "in respect of every public office or employment of profit." Rule 9 of this schedule allows a deduction of expenses "necessarily incurred and defrayed" in travelling in the performance of the duties of the office or employment or" (a pleasant old-world touch) "keeping and maintaining a horse to enable him to perform the same," or otherwise spending money "*wholly, exclusively, and necessarily in the performance of the said duties*" No-one, of course, expects the Inland Revenue to be soft-hearted in applying these words which we have italicised. An air pilot was not allowed to deduct the cost of a telephone to his house. The nearest case for our present purpose is Simpson *v.* Tate where in 1925 Mr. Justice ROWLATT held that a county medical officer was not entitled to deduct the cost of subscriptions to medical and other professional societies. "I think," said the learned judge, "that all subscriptions to professional societies and all taking in of professional literature and all that sort of expense which enables a man to keep himself fit for what he is doing are things which can none of them be allowed. If they were allowed, every professional man would say: 'I have to belong to this and I have to belong to that society; I have to take in this publication and I have to take in that publication, and to do all sorts of things,' and there would be no end to it. I think the principle is quite clear; nothing of that sort can be allowed." The latest edition of Judge KONSTAM's *Law of Income Tax* observes that this decision seems doubtful. It was followed nevertheless in 1945 in Blackwell *v.* Mills where there had been a condition in an employee's contract of service that he should attend classes at the Chelsea Polytechnic; the expense of the classes was not allowed as a deduction. One other case is worth noting—Wales *v.* Graham, in 1941. Here the taxpayer, a divisional engineer employed by the London County Council, sought to deduct the cost of his subscription to the Institution of Civil Engineers. Candidates for the post of divisional engineer had to be corporate members of the institution or to hold qualifications approved as equivalent. It was not specifically required that membership of the institution should be continued after the candidate was appointed, but there was substantial evidence that relinquishment of membership would make impossible the continued efficient discharge of the full duties of the office. The Crown argued that the subscription to the institution was not money expended wholly, exclusively, and necessarily in the performance of the taxpayer's duties: it was not enough to show that it was "necessarily" incurred to secure or retain the appointment or to obtain promotion in the service The court refused to allow the deduction.

Private practitioners are assessed, of course, under schedule D of the Income Tax Act and not under schedule E. This seems to permit a slightly more generous attitude. Where schedule E speaks of sums "wholly, exclusively, and necessarily expended in the performance of the duties of the office or employment," schedule D speaks of sums "wholly and exclusively laid out or expended for the purposes of the trade or profession." Significance is attached to the word "necessarily" in schedule E and to the words "purposes of the profession" in schedule D There seems no reason why the expense rules should be more niggardly in the one case than in the other Practitioners in medicine and surgery who serve in H.M. Forces are not unreasonable in thinking themselves at some disadvantage in their efforts to keep abreast of current developments. Their anxiety to give of their best should not be taxable.

Among the expenses "necessarily and reasonably incurred" by specialists "in the course of their work," the last Spens Committee includes "the cost of books and journals, preparation of scientific papers, and subscriptions to professional societies" and it presumes that the Inland Revenue authorities "would be prepared to consider favourably as legitimate allowances for income-tax purposes any items of expense which had been approved by a public hospital authority." We hope that the Minister of Health may indeed be able to persuade the Treasury to take this wise view.

Leptospirosis Canicolaris

CANICOLA fever (leptospirosis canicolaris) in man provides some puzzles for both the clinician and the epidemiologist. The organism, *Leptospira canicola*, primarily infects dogs, and in all countries where serological surveys have been made a considerable proportion of the canine population shows evidence of past infection. STUART[1] obtained 40% of positive reactors among street dogs in Glasgow, and BROOM and MACINTYRE[2] found 26% of positives among dogs from different parts of England. In spite of this high proportion of infection among dogs, only 100 human cases have been diagnosed during the fourteen years since *L. canicola* was first isolated from dogs and man by DHONT and others.[3] The distribution of these cases was listed by Dr. MINKENHOF in his paper last week, and it is noteworthy that, though the disease has been reported from many parts of the world, no less than 61 of the records come from Holland and Denmark. The work of SCHÜFFNER and his co-workers has led to a general awareness of leptospirosis in Holland, and all sera sent to the State Serum Institute in Copenhagen for Widal tests are also examined for leptospira agglutination.[4] It may be therefore that the figures for these countries give the best indication of the general prevalence of the disease. If so, a large number of cases go unrecognised elsewhere.

So far as is known, *L. canicola* is not carried by rodents, like other leptospiræ; so dogs are the only important source of infection. The disease in dogs has not yet been fully elucidated, but nephritis is usually the outstanding feature. If the dog recovers, leptospiræ continue to be shed in the urine for a variable period, generally a few months but occasionally a year or more. Direct transfer of leptospiræ by infected urine is probably the common method of spread among dogs, and also from dog to man. This is well illustrated by the cases described by Roos et al.[5] and by SENTHILLE et al.[6] In each of these instances a bitch and her puppies were excreting leptospiræ, and canicola fever developed in their owners and also in people who received puppies. It is possible to trace the source of infection by laboratory tests in many cases, but not in all. In the case described by BABER and STUART[7] the patient had had no apparent contact with dogs, and these workers consider the possibility of infection while bathing. This is of course a well-recognised means of contracting Weil's disease. Rivers, ponds, and especially stagnant water are contaminated by rat urine containing *L. icterohæmorrhagiæ*, and the organisms probably gain access to man through the conjunctiva or tonsils.[8] In Holland VAN THIEL[9] found that *L. icterohæmorrhagiæ* could retain its virulence for at least twenty-two days in muddy water, and he suggested that canicola fever also might be contracted in water fouled by dogs which were excreting *L. canicola*. WINSSER[10] thinks that dogs too sometimes become infected through contaminated water, because a history of direct contact could not be established in some of his canine cases. Little is known about the capacity of *L. canicola* to infect man. Rodents and other small laboratory animals, however, are highly resistant; guineapigs generally show merely a transient infection, and the hamster (*Crycetus auratus*) is the only animal in which fatal leptospirosis occurs consistently. These findings, together with the considerable chance of contact with infection which the close dog-man association must entail, suggest that the pathogenicity of *L. canicola* is in fact low for humans, but much more information is required on this question.

Canicola fever is classed among the benign leptospiroses, and only one fatal human case has been described.[11] The clinical signs and symptoms are very variable. WALCH-SORGDRAGER[12] drew attention to the relative frequency of meningeal signs, and further experience has confirmed her observation. As a rule the onset is abrupt with fever, vomiting, muscular pains, intractable headache, and some stiffness of the neck. The patients are often admitted to hospital with a diagnosis of poliomyelitis or serous meningitis. A variety of eye signs may appear during the illness—conjunctival or ciliary congestion, photophobia, mistiness of vision, blurring of the optic disc, and optic perineuritis. SNAPPER et al.[13] noted the development of vitreous opacities in one patient eight months after recovery. Similar eye signs arise in meningitis due to *L. icterohæmorrhagiæ*.[8] Abdominal pain and vomiting are common in canicola fever, and the liver and spleen are occasionally enlarged, but jaundice has been recorded in only 6 cases. Rashes of various types are described, and a few cases have had epistaxis, but severe hæmorrhages such as occur in Weil's disease are seldom seen. Acute nephritis is typical of the disease in dogs, but it has been recorded only a few times in man—for example, in the severe case reported by MEYER et al.[14] where both jaundice and nephritis were well-marked. In most of the reported cases the urine has contained albumin with erythrocytes, leucocytes, and casts, but only for a short period, and the blood-urea has been within, or slightly above, normal limits. When more cases are brought to light it may be found that, as in Weil's disease, the symptoms are either mainly meningeal or mainly hepatorenal in origin. In meningeal cases the protein content of the cerebrospinal fluid is raised. Either segmented or mononuclear cells may predominate. The number of cells may be normal in the early stage and increase later, as in the case described by Dr. LAURENT in the symposium published in this issue; or the rise may occur in the first few days as in Dr. NORRIS's first patient. The variability of the symptoms makes clinical diagnosis difficult, and in the past a correct decision has not usually been reached until the later stages of the disease. When a rash is present syphilis, the exanthemata, and various skin diseases

KEKWICK and his colleagues[1] at the Lister Institute, and already experimental batches of this globulin are being tested in controlled clinical trials with encouraging results. Meanwhile, until supplies become more generally available, normal adult serum, which is distributed by the Public Health Laboratory Service, may be used in doses of 5–10 ml. to modify the attack in young children.

There are other uses for gamma-globulin. It has already proved effective in the prophylaxis of infective hepatitis, and has even had some success against upper respiratory infections.[2] Like other preparations, it has failed to abort the paralytic stage of poliomyelitis and has given negative results in the control of chicken pox and mumps. Here it may be necessary to prepare a concentrated globulin from pools of convalescent serum; in one study[3] such a globulin apparently reduced the incidence of orchitis when given in doses of 20 ml. after the onset of mumps in young adults. We do not yet know whether it will protect the pregnant woman against rubella; but we can fairly hope that this substance, originally almost a waste product, will prove an effective new weapon against the still intractable virus infections.

A Tax on Knowledge

FROM time to time attention is drawn to the discouraging attitude of our income-tax law towards such professional expenses as the purchase of textbooks and scientific journals and subscriptions to societies. A correspondent serving in the Forces complains that no rebate is allowed him in his efforts to use these means of keeping abreast of current medical knowledge on a fixed salary. He suggests that a medical man in the Services is in this respect denied privileges which civilian doctors enjoy. But subject to the mysterious distinctions discoverable in the expense rules under schedules D and E, it does not appear that civilians obtain much greater advantage from the Inland Revenue than doctors serving in the Navy, Army, or Air Force.

The material passage for the latter seems to be found in schedule E, which charges tax "in respect of every public office or employment of profit." Rule 9 of this schedule allows a deduction of expenses "necessarily incurred and defrayed" in travelling in the performance of the duties of the office or employment or" (a pleasant old-world touch) "keeping and maintaining a horse to enable him to perform the same," or otherwise spending money "*wholly, exclusively, and necessarily in the performance of the said duties.*" No-one, of course, expects the Inland Revenue to be soft-hearted in applying these words which we have italicised. An air pilot was not allowed to deduct the cost of a telephone to his house. The nearest case for our present purpose is Simpson *v.* Tate where in 1925 Mr. Justice ROWLATT held that a county medical officer was not entitled to deduct the cost of subscriptions to medical and other professional societies. "I think," said the learned judge, "that all subscriptions to professional societies and all taking in of professional literature and all that sort of expense which enables a man to keep himself fit for what he is doing are things which can none of them be allowed. If they were allowed, every professional man would say: 'I have to belong to this and I have to belong to that society; I have to take in this publication and I have to take in that publication, and to do all sorts of things,' and there would be no end to it. I think the principle is quite clear; nothing of that sort can be allowed." The latest edition of Judge KONSTAM's *Law of Income Tax* observes that this decision seems doubtful. It was followed nevertheless in 1945 in Blackwell *v.* Mills where there had been a condition in an employee's contract of service that he should attend classes at the Chelsea Polytechnic; the expense of the classes was not allowed as a deduction. One other case is worth noting—Wales *v.* Graham, in 1941. Here the taxpayer, a divisional engineer employed by the London County Council, sought to deduct the cost of his subscription to the Institution of Civil Engineers. Candidates for the post of divisional engineer had to

evidence against the day in the late 'sixties when the country was ready for the next step—a Royal Commission.

Then there was Mr. Beaumont of East Bridgford, in Nottinghamshire, who insisted on giving evidence to the commission. Pollution of the Trent by Nottingham, higher up the river, had brought fever to his village; and when he had read up "everything in the way of Acts of Parliament and handy books to get up the question" he had found them unintelligible. The cholera epidemic of 1866 contributed its share to the change of temper. The feminist movement turned slumming ladies into practical social workers, and Mrs. Baines, addressing the Manchester Statistical Society, foreshadowed the great body of women social workers on which our modern public-health service is largely based, when she said: "If the women of England could be so persuaded, we might raise up a whole army of women workers in this hitherto neglected field." Public imagination was stirred in another way when, in the famous five-case outbreak, typhoid struck the Prince of Wales, an earl, a butler, an indoor servant, and a stable-boy. In this social hierarchy, the butler and the indoor servant suffered lightly, the earl and the stable-boy perished, and the Prince was in danger of death.

The result of all was an Act of which no one thought much at the time—a patchwork, workaday Act, to amend and consolidate existing sanitary law, passed quickly in a defeatist mood at two consecutive sittings between tea and dinner, with the Derby in between. Yet, says the report, "it would be difficult to pick out any piece of defunct legislation and say that it had been in its day a better and more faithful social servant than the Public Health Act, 1875." Its successors in 1906 and 1925, the Ministry of Health Act, 1919, and the Local Government Act, 1929, have all been part of a piecemeal development along the same lines, giving us "good services but a bad service."[2] Now, in 1948, the temper of the times demands a fresh grouping. What seems a tidal wave to us is perhaps after all no more than the seventh breaker travelling a little farther up the beach.

MAN INTO WOLF

Even if Singh and Zingg[3] had not lately collected and published authentic instances of "feral man," no-one could now doubt that human beings have at times abjured, or failed to acquire, human behaviour. Their adoption of many of the habits of beasts has often been the outcome either of mental disease of upbringing by a feral fostermother—especially olf, as in the striking instance related by Gesell,[4] the earlier more famous one mentioned by Livy. Robert Eisler, however, in a lively address to the ion of psychiatry of the Royal Society of Medicine June 8, took a bolder, wider view of the genesis of ine traits in human beings. Ranging freely through hropological and psychopathological data, and with ch evidence of philological virtuosity, he examined sadism and masochism, especially the latter, and w a distinction between algolagnia and algobulia—a n he coined forty years ago to denote an enjoyment pain which could not be regarded as a perversion. his view sadism and the qualities related to it are human; it is scarcely correct to call them atavistic, by atavism one means reversion to the primitive age, since primitive savages are neither the noble iple men of Rousseau's imagining nor the cruel and rlike creatures we know in some peoples. But reversion re certainly is. Originally, long before Neanderthal Piltdown man, we were frugivorous and mild; at some remote time a change occurred, and man became capable of murder and warfare. Many myths and folklore tales refer to this change and to the persistence in women of man's original gentleness. The names of many tribes and groups—e.g., the Lycians—attest the wolf-like qualities they developed as the result of some mutation, so that they came to imitate the behaviour of predatory animals like wolves. Hence the werewolves who have been described in so many countries; hence also the survival of wolf-like religious rituals, as in North Africa today (Dr. Eisler illustrated this with slides of a dilaniating sheep-clad officiant in Morocco). Dr. Eisler's exposition followed a line of thought akin to that of C. G. Jung in his theory of archetypes, and still more reminiscent of the pseudobiological speculations of the late F. G. Crookshank.

THE NEGLECTED CHILD IN HIS OWN HOME

The Curtis report on children deprived of a normal home life called attention to the many other children "who, though suffering neglect, malnutrition, or other evils, are still in their own homes under their parents' care." Such children, who are equally deprived of a "normal" home life, are the subject of a study[1] made last year by a committee of the Women's Group on Public Welfare, in association with the National Council of Social Service—the same group whose book *Our Towns*, published a few years ago, threw into such clear relief the social conditions revealed by evacuation. The children affected in this new inquiry, though only a small proportion of the total child population, are exceedingly numerous. Thus in 1944–45 alone the National Society for the Prevention of Cruelty to Children dealt with 107,312 children coming from 41,050 families—nearly as many as the whoel group of deprived children studied by the Curtis Committee. Wilful physical cruelty is uncommon, and fortunately getting rarer. Thus in Liverpool there have been 7000 recorded cases of neglect in the last ten years, but only one case of cruelty in each of the last two; and similar figures are reported elsewhere. "Neglect" has been interpreted by the Women's Group as "failure to make adequate provision for the physical, emotional, and intellectual needs of a child"; and this includes gross failure to provide affection and security. Yet it is evident that even a neglectful mother can often give her children a sense of security scarcely to be replaced in any other way: "the unhappiness of the victim . . . at being parted from the offender" greatly complicates the management of these cases. And indeed the offender is often herself a victim. She is most commonly, as Mr. J. B. Priestley says in a preface to this report, "an unhappy creature who is by no means a thoroughly bad sort, who is not really mentally warped, but who, because of ill luck, indifferent health, too much child-bearing, a poor fish of a husband, or no husband at all has just let things slide and slide until at last she cannot even pretend to be coping with her job as a parent." Mothers sentenced for child neglect, the Women's Group found, gave as explanations of their offence such things as bad housing, lack of money, and lack of anyone to look after the children while they were away at work or elsewhere. Often a neighbour had accepted responsibility and then let them down. Not one of the mothers gave ill health as a reason for their failure, though 75% of them were below average health standards when sentenced.

The Women's Group think prison an ineffective remedy in such cases; and indeed it is doubtful whether most of the mothers would be sentenced if they had someone to plead their cause. Set before a prosecuting solicitor and a magistrate, the dazed uncomprehending woman hears herself committed to prison, or learns that her children

must be excluded. Other cases may have to be differentiated from poliomyelitis, meningitis of bacterial or virus origin, acute nephritis, or the various forms of hepatitis. The similarity of the symptoms to the meningeal form of Weil's disease or to "swineherd's disease"[15] may suggest leptospirosis, but the diagnosis depends finally on laboratory investigations. If leptospirosis is suspected during the first week, the organism may be isolated by inoculating blood and cerebrospinal fluid into hamsters and into appropriate culture media. The agglutination reaction usually becomes positive about the eighth to tenth day, but the appearance of agglutinins is delayed in some cases. Repeated tests should be done, especially when penicillin treatment has been given, because there is some evidence that this drug curbs the production of antibodies, perhaps by reducing the number of leptospiræ and so lessening the antigenic stimulus. During the third and fourth weeks leptospiræ may be present in the urine, and, provided the specimen has been made slightly alkaline, the organisms can be isolated from this by animal inoculation. Only very rarely can leptospiræ be found in wet blood films, but "blood filaments" derived from the cells are fairly common, and these fine threads often seem motile because of the brownian movement of particles in the fluid; this is a likely source of error. Treatment in most cases has been symptomatic because of the difficulty of early diagnosis. There is as yet no specific antiserum, and *L. icterohæmorrhagiæ* antiserum would be ineffective since there is no cross-protection between the two types of leptospira. The relatively benign character of the human disease makes it difficult to assess the value of drug therapy in man, but penicillin has given strikingly good results in dogs.[16]

Annotations

SIR RONALD ROSS

WHEN, in July, 1898, Ronald Ross finally established the mosquito theory of the origin of malaria, he cleared a path along which we have travelled far enough for the control of this disease to be a routine and its extermination a vivid possibility. Ross's early studies, after he joined the Indian Medical Service in 1881, were undertaken in ignorance of Laveran's identification, in 1880, of the malaria parasite. But while in England in 1894 he met Patrick Manson, who showed him the parasites and suggested that they might be transmitted from man to man through the mosquito. Returning to India the next year, he set out to discover what happened when the blood of a malaria patient was swallowed by a mosquito; and after many disappointments he proved, on Aug. 20, 1897, that the mosquito was the intermediary in transmission.

This week the Ross Institute marked the jubilee of the completion of this work, by a reception and an exhibition. Here were to be found Ross's letter to Manson, recording step by step the course of his labours. Here also was depicted the gradual, and still evolving, mastery of the infection from the day that his work in India ended. Even after 1898 all was not easy for him. Part of his life was embittered by rival claims to those laurels that were properly his; and, as often happens with people that have something new to say, he had to overcome what Mr. John Masefield (speaking at the reception) stigmatised as "the vast dark sullen apathy of the multitude of man." The full significance of his discovery came to be recognised through his own application of it in Sierra Leone and elsewhere, through Sir Malcolm Watson's initiative in Malaya, and through successful imitation by others. By the time that he died, in 1932, he knew that his place in history was assured.

Though no dilettante, Ross was a man of many interests, ranging from research on pure mathematics to the devising of a system of phonetics. He chose, too, to express himself in poetry, of which the Poet Laureate said: "If the verse will jar your ear, the intelligence will jar your complacency." The passing of the years has underlined our debt to him. As Ross himself said in his Nobel prize lecture: "The spring had been touched, the door flew open, the path led onward full in the light, and it was obvious that science and humanity had found a new dominion."

CAVALCADE OF PUBLIC HEALTH

A HUNDRED years ago, when the first Public Health Act was passed, the sanitarians were playing for high stakes, since the future of industrial civilisation depended largely on their success. The Industrial Revolution had huddled its rapidly recruited army of wage-slaves into a squalor which inevitably bred pestilence; long years of uncontrolled industrialism had blighted great areas of our towns, and stunted the men and women in them. Much of that blight is still with us as a main obstacle to decent town life; but even by the end of last century, with sanitation under way, attention could be turned to the national physique, whose deterioration was bitterly deplored with each threat of war. How the empire of public medicine gradually widened by stages is shown in the "cavalcade of public health" so cleverly presented in the latest annual report from the London School of Hygiene and Tropical Medicine.[1] First there was the pioneering of the personal health services, the school medical service, maternity and child welfare, and the tuberculosis services. And then came modern State provision for the sick, with home doctoring under National Health Insurance, and the provision of public general hospitals after 1929. Each service was good of its kind but developed in isolation from the others.

In 1854, when the General Board of Health, of which Chadwick was chairman, was undermined by opposing public opinion and lost most of its powers, it was felt that the Public Health Act of 1848 had miscarried. Yet, as Disraeli was to say twenty years later, "In legislation it is not merely reason and propriety which are to be considered, but the temper of the times." The "cavalcade" shows that the subtle change in the temper of the times between 1854 and the passing of the next Public Health Act in 1875 was brought about less by reforming zeal than by hard work and [illegible] accidents. Much of the hard work was done by F[illegible] and Simon. Dr. William Farr, of the Registrar-General's office, was a statistician with a vivid pen who brought the confused facts of sanitary science "into light, harmony, and order." He had a skilful disseminator of his vital statistics in Sir John Simon, M.O.H. for the City of London. Simon piled up news of yellow fever brought by barques from Cuba, distress in Lancashire from the cotton famine, cholera brought by Ba[illegible] emigrants, malaria in the Isle of Sheppey, epidemics [illegible] smallpox, typhus, typhoid, and scarlet fever. Fr[illegible] such facts he built his famous reports—a mass of ha[illegible]

BRITISH MEDICAL ASSOCIATION

IN dull weather with bright intervals the association last week concluded the first annual meeting it has held for nine years. The attendance was larger than might have been expected in the difficult circumstances, and Cambridge left nothing undone to give its visitors a stimulating and refreshing few days. For the two great receptions, presidential and civic, the Old Schools provided a noble setting; and a most friendly welcome as given in the colleges.

At the annual dinner the VICE-CHANCELLOR (Canon aven) and the MAYOR (Mr. G. F. Hickson) replied to e toast of the University and Town of Cambridge, oposed by Sir HUGH LETT. Prof. G. M. TREVELYAN, M., spoke of the zealous care given to the people of his n countryside by their doctors, "a willing service that o private fees nor State salary can buy." That 50 illion people could live in so small an island as ours as due, he thought, as much to the work of doctors as f captains of industry, and their part was more innocent. r. GUY DAIN described the B.M.A. as a voluntary ssociation of doctors to preserve their honour and nterest: who else was in a position to hold together the arious sections of the profession? This year it had chieved what had never been done before: it had organised, or modified the organisation of, a service in which the freedom of the profession and the public were preserved. "We are on the point of starting a service such as has never before existed." Now that the struggle was over and freedom had been attained, doctors would put their best efforts into making it a really fit and proper and good service. But the price of freedom was still eternal vigilance, and that would be the B.M.A.'s work. Dr. V. H. L. ANTHONISZ (Ceylon) was also hopeful, though the National Health Service would no doubt suffer from infantile troubles such as convulsions and growing pains, as well as "the difficulties attending the arrival of an unwanted child." Responding for The Guests, proposed by Dr. ROBERT ELLIS, the LORD LIEUTENANT (Capt. R. G. Briscoe) said he had known for some time that something awful was going to happen in 1948, "because here in Cambridgeshire we've had the worst apple crop for many years." And finally Sir LIONEL WHITBY replied to the toast of The President, proposed by his professorial colleague, Dr. E. D. Adrian, O.M.

On Friday evening Sir HENRY DALE, O.M., delivered the popular lecture on Accidents and Opportunism in Medical Research.

Scientific Sections

MEDICINE

President: Dr. LESLIE COLE

Thiouracil in Thyrotoxicosis

Wednesday, June 30, was cold and wet; but neither cold, rain, nor poster maps prevented the assembly of a fair crowd to hear Prof. H. P. HIMSWORTH's vigorous defence of thiouracil. This drug, he said, can certainly bring the symptoms of thyrotoxicosis rapidly under control, and it is now known that an initial dose of 200 mg. a day of methyl thiouracil, followed by a maintenance one of 25–50 mg. a day, is usually just as effective as the much larger doses formerly used. Of his cases treated for between nine and twenty-one months two-thirds have secured a long remission. Judged by symptoms, gain in weight, pulse-rate, effects on lid-retraction, and so on, thiouracil is as effective as surgery, except that it only rarely gets rid of the goitre. Harmless toxic reactions occur in 10% of cases, but granulocytopenia in only 2%; and with early diagnosis, and penicillin treatment, only 25% of the latter, or 0·4% of all cases treated, die of this complication. Regular white-cell counts are worse than useless in guarding against agranulocytosis, because they give a false sense of confidence. Patients should be told to consult their doctor immediately if they have fever, sore throat, or any illness, and the doctor should simply examine a stained blood-film to see whether polymorphs are deficient or not. There is no danger of producing carcinoma with therapeutic doses. Pressure symptoms, a suspicion of malignancy, and the occurrence of agranulocytosis during thiouracil treatment are absolute indications for surgery. For the rest, the mortality from surgery is 2% in the best hospitals, and considerably higher elsewhere. Thiouracil can do all that surgery can, with a mortality of 0·4% and at a cost simply of swallowing one small tablet each evening.

Mr. CHARLES DONALD, dismissing the Gospel according to Gower Street in favour of the Book of the Word from Whitechapel, had little use for figures. Control with thiouracil, he said, is no more than a damping-down of symptoms which makes life more or less tolerable. Some patients who had been treated with apparent success with thiouracil, and had afterwards come to thyroidectomy, said they had thought they felt well while on the drug, but after operation they knew what it was to feel really well. Thiouracil means a long period of therapy under constant supervision, during which the patient is often made into an invalid. The mortality from surgery should not be greater than 1%. It offers dramatic and immediate amelioration of symptoms, a rapid return to normality, a surer return to health, and a relapse-rate of less than 5%.

Subsequent speakers made useful contributions in an attempt to resolve this conflict of opinions. Thiouracil, it seems, is admittedly better than a bad surgeon. There is still much to be learnt about its use, and better thiouracil may some day be better than any surgeon, in properly selected cases. Meanwhile, thiouracil has made surgery much safer, and thiouracil followed by operation is possibly, for the moment, the treatment of choice in the majority of cases. Dr. COLE has found thiouracil of particular use in the treatment of exophthalmic ophthalmoplegia, and for therapeutic test in the diagnosis of doubtful cases of toxic goitre.

Phonocardiography

Dr. E. D. H. COWEN gave a lucid explanation of phonocardiography and showed two patients to illustrate the kind of problems it may help to solve.

Surgery in Hypertension

Thursday morning was merely bitterly cold, but a combined meeting of the sections of medicine and surgery crowded the zoology theatre to hear Dr. R. H. SMITHWICK (Boston, U.S.A.). He confined his remarks to 256 cases he has been able to follow for from five to nine years. Distinguished pioneer of the subject that he is, his contribution dwarfed that of anyone else; but his work must be read in detail. Hypertension, he said, kills more people than cancer: has surgery anything to offer? Of five different techniques for sympathectomy, he favours for most purposes that which removes in two stages the sympathetic chain from the 8th thoracic to the 1st lumbar ganglia, together with both splanchnic nerves. His operative mortality has been 2%. Mortality in the months after operation is highest below the age of twenty and over the age of fifty, but depends on the state of the patients before are to be committed to others until they are 18 or for a period to which no term may be set. The Women's Group recommend that parents should be legally represented when charged with cruelty or neglect, and that the power of placing parents on probation should be more freely and fully used. A child, they consider, should not be removed from his parents until the question of keeping the family together has been fully examined. They describe various schemes for training the mother in her craft, including the residential recuperation home for mothers with their children set up by the Community Council for Lancashire at Brentwood, near Manchester. They also advocate more "rest break" and holiday homes for mothers, development of home-help schemes, and an extension of family case work by local authorities, either directly or through voluntary bodies.

RESEARCH ON PHYSICAL FITNESS

THERE are good reasons why the interest in physical fitness, renewed by the war, should be sustained. The term has a wide usage, both lay and medical: the doctor is interested in the fitness of his patients for various types of work, the physical educator in the athletic skill and precision of his pupils, the manufacturer and the State servant (civil or military) in the efficiency with which a job of work is done. Yet the physiologist and the psychologist, on whom we must depend for clarification and systematisation in this field, have as yet only stalked warily round the hedges. The wariness extends beyond the laboratory, too, and is the chief characteristic of a recent American report by a subcommittee of the Baruch Committee on Physical Medicine.[1] The authors of this report point out that at least four aspects should be included in any tests or survey—(1) general cardiovascular, respiratory, and neuromuscular fitness and efficiency for moderate prolonged or rapid exhausting work; (2) skill and agility of the neuromuscular system, partly inborn and partly acquired; (3) special physical strength for specific heavy or exacting tasks; and (4) motivation, the will to carry out the task to the very best of one's ability.

The various physiological tests of the first three aspects have lately been summarised and discussed in Cureton's book,[2] half monograph, half textbook. Both constitutional factors (notably physique and sex) and more transitory disturbances (such as "a night out") affect the various test scores. It has been shown, for instance, that women, on the average, have a higher blood lactic acid after moderate exercise of a few minutes' duration than do men.[3] Trained men produce less lactic acid than untrained,[4] and men suffering from a neurosis produce the highest lactic-acid levels of all, as has been shown by Maxwell Jones and his associates.[5] [6] Thus the lactate levels parallel the degree of fatigue complained of by each group.

Two recommendations of the subcommittee will, we believe, be enthusiastically received. First, "the routine medical history and physical examination can and should do more than assess physical defects": it should include tests designed to measure aspects of fitness. Secondly, the medical schools, and especially the departments of physiology, should spend more time teaching the student the reactions of the intact healthy human organism to various stress conditions, as is now done by Professor Landis at Harvard.[7] In such an endeavour psychologists should also have their say. We may hope that in this way both fundamental research and its intelligent application would be fostered.

PAIN IN ANIMALS

THE humane will welcome guidance about the capacity of animals to feel pain. In a pamphlet,[1] published by the Universities Federation for Animal Welfare, Mr. John R. Baker, D.SC., reviews the evidence.

Human reactions to pain and fear are a struggle to escape, contortions of the body and particularly the face, and production of mournful sounds; and we are likely to attribute sensations of pain to an animal which shows any of these manifestations. But we cannot always be certain that their presence indicates pain or their absence the lack of it. Thus a frog whose brain has been destroyed will still draw its foot away from the touch of acid, and a mollusc, which has no gift for flight, cannot betray pain by an effort to escape. Animals that live in groups, especially when the young are tended by parents, are apt to call attention to pain in ways that resemble our own. A non-social animal, on the other hand, gains no help or consolation by calling attention to pain or fear; and may mislead us by its silence and stillness. Psychological fear, from memory and apprehension, is probably confined to the higher animals: those in which the cerebral hemispheres are poorly developed may experience immediate pain through the thalamus, but are likely to suffer less than man from memory of past pain or fear of pain to come. The vertebrates, with a nervous system akin to our own, are presumably able to feel pain in the same sorts of way as we are, but the primitive invertebrates, with a diffuse nerve-net and no cerebral ganglia, cannot be supposed to be any more "conscious" than our own bowels, which can be cut and handled painlessly. "We can only base our opinions as to whether invertebrate animals are conscious of pain," Dr. Baker says, "on considerations of the size, complexity, and degree of integration of the nervous and sensory systems, and on the intelligence of the animals as shown by their capacity to learn and adapt their behaviour to unusual circumstances." He credits the higher arthropods and molluscs with consciousness; which suggests that those who feel uncomfortable about the boiling of lobsters are only too right

WORLD HEALTH ORGANISATION

THE World Health Assembly last week unanimously decided that the headquarters of W.H.O. shall be in Geneva. This decision is subject to final confirmation by the General Assembly of the United Nations, but no opposition is likely. The British Government's tentative invitation to the organisation to bring its headquarters to England[2] was withdrawn some weeks ago.

ROYAL SOCIETY OF MEDICINE

LAST Tuesday, at the annual meeting of fellows, Sir Maurice Cassidy, the president, presented the diploma of honorary fellowship to Sir Archibald Gray, Prof. Charles Singer, and Sir Henry Tidy. The other three recipients are Prof. Georges Debaisieux (Louvain Dr. Mathew Makkas (Athens), and Field Marshal Smu Sir Henry Dale, O.M., G.B.E., F.R.S., was elected president for 1948–49. The society now has 9028 fellows, member and associates, of whom 1290 live abroad.

Dr. J. W. S. BLACKLOCK, professor of pathology at Glasgow since 1937, has been appointed to the university chair of pathology tenable at St. Bartholomew's Hospital. Dr. James Whillis has succeeded to the chair of anatomy at Guy's Hospital.

and the results, though not perfect, were better than with any other. In the light of over 300 cases, most of which had been followed up, Mr. Ronald Reid thought that constitutional treatment in an institution, assisted sometimes by splinting of the neck, and sometimes by tonsillectomy, should be continued until the glands became quiescent. Only then should diseased glands be removed, through a transverse incision. Block dissections and chasing of gelatinous glands up and down the neck were condemned. In 291 of the 302 cases followed up there had been no recurrence of the glands. One case had subsequently developed tuberculous meningitis and two pulmonary tuberculosis.

Tuberculous mediastinal glands are very difficult to diagnose, in Mr. Hugh Reid's experience, and these cases may present as bronchitis, bronchopneumonia, or collapse, or as general malaise and listlessness. He thought that tuberculous mesenteric adenitis might be treated either conservatively or by appendicectomy. He regarded the appendix as a sort of abdominal tonsil.

Other speakers deplored the almost insuperable difficulty of getting patients with tuberculous adenitis into sanatoria. Many of the physical methods used were condemned as attempts to do something, faute de mieux. The real treatment of tuberculous glands was to prevent the sale of tuberculous milk. Only Mr. F. Stock advocated radical excision of abscess cavities and outlying glands; most speakers favoured small incisions, some with judicious use of the sharp spoon: bipp was not considered of much use. Hamilton Bailey's method of excising skin and leaving the wound to granulate found some support in cases with sinuses. Mr. R. D. Porter mentioned that he had sectioned 200 " cold " appendices and found evidence of tuberculosis in 20%.

Treatment of Carcinoma of the Breast

In discussing the lymphatics of the breast, Sir Cecil Wakeley pointed out that there were no direct connexions between the breast and the supraclavicular glands; so if these were involved they were invaded via the internal mammary chain. Nor did the apical axillary glands drain into the supraclavicular glands. The symptoms which brought the patient to the doctor were a lump in the breast and pain, and pain was a late symptom. Any doubtful lump in the breast should be excised and examined histologically. The laity should be convinced that early cancer of the breast was curable. In stage-I cases—i.e., those with no enlargement of axillary glands—radical mastectomy was the treatment of choice. If the growth was in the inner part of the breast the internal mammary glands might be invaded, though there was no clinical indication to show that the growth had in fact become a stage-II growth. In stage-II cases preoperative irradiation should be followed by radical mastectomy. For stage-III and stage-IV cases, irradiation was the treatment of choice. Testosterone should be given an extended trial in stage IV. A common error of treatment was to underestimate the extent of the disease and under-operate or under-irradiate. Deep X-ray therapy should be standardised. Lack of facilities for X-ray treatment throughout the country was largely responsible for the poor results. Dr. Frank Ellis preferred deep X-ray treatment to radium as a means of irradiating breast cancers, because it was more uniform in application. Radium gave a localised effect, too much so for treating the internal mammary lymphatic chain (which could well be irradiated with deep X rays), and in the axilla it tended to cause brachial neuritis. Dr. Ellis did not fully agree with Professor McWhirter on the desirability of irradiation and simple mastectomy. Many fallacies crept in when comparing different series of cases. Mr. J. B. Oldham contended that the chief factor in getting cases too late was economic. The busy mother or the self-supporting spinster felt she could not afford the time off work. The public still often believed that cancer was painful in its early stages. All stage-II cases should have preoperative irradiation. In operable cases, a radical mastectomy was more important than radiotherapy. Like Sir Cecil Wakeley, he thought that radical mastectomy should start with the dissection of the axilla, and the brachial artery and nerves should not be stripped bare.

In Mr. R. L. Holt's view we had not advanced far from Halsted's results. Halsted had found that 2 early cases out of 3 could be cured, but when the axilla was involved 3 out of 4 succumbed. There was still great divergence of opinion among leading authorities on the best form of treatment. Radical mastectomy gave much better results in stage I and II than some enthusiastic radiotherapists would lead one to believe, but it must be done well. Radiotherapy was a " holding " treatment, and a series of over 100 cases treated at the Christie Hospital initially with X rays and subsequently operated on showed that there were viable cancer cells in the treated areas in 80% of cases. In another series treated by X rays it was found that the longer the patient survived the more certain was it that the primary tumour would show signs of reactivity. Radium was on the whole more effective than X-ray treatment, but it was more difficult to get even dosage. Radiotherapy had not greatly improved the results of surgery. The real answer to the problem was to get the cures earlier and to teach students that the so-called signs of malignancy in the breast were signs of late malignancy. Mr. R. S. Handley thought that the reason why 25% of stage-I cases subjected to radical mastectomy died within five years of operation lay in invasion of the internal mammary glands. He had explored the 2nd or 3rd intercostal space in 31 cases of carcinoma of the breast and Dr. A. C. Thackray had found invasion of the internal mammary chain in 15 cases. Three of these 15 cases had had no deposits in the axilla and would have been looked on as stage-I cases if the intercostal space had not been explored. Mr. James White pleaded for hormone treatment in late cases and showed X-ray films of pelvic deposits which had almost disappeared under androgen therapy. Prof. E. F. Finch mentioned leucotomy in cases of intolerable pain with untreatable secondary deposits. He urged that the treatment of cancer cases did not finish when the growth had been operated on.

The *Surgery of Hypertension* was discussed jointly with the section of medicine (see above).

ORTHOPÆDICS

President: Prof. T. P. McMurray

Lesions of the Intervertebral Discs

The differences of opinion on this subject are still capable of introducing a certain amount of passion into debate.

Prof. Norman Dott (whose paper was read, in his absence, by Mr. G. L. Alexander) indicated the size of the problem by estimating the incidence of new cases of lumbago-sciatica due to disc prolapse at something like 300 per million of the population per annum. From the standing position, with its evolutionary weakness, the lesion throws the sufferer back to an older and more crouching attitude. Though the hazards of the upright posture are unavoidable, physical unfitness should be prevented, for it predisposes to the common causative " trauma in suprise," when weak postural muscles are caught off their guard; a significant local trauma of this kind occurs in half the cases, while the strain of pregnancy is also a common factor. There are several types of prolapse, and it is easy to miss a small lateral protrusion at the intervertebral foramen or the diffuse bulge caused by nuclear rupture into the annulus. The escape of free nuclear material into the epidural fat sometimes provokes a chronic granulomatous reaction, with severe symptoms and a greatly raised protein level in the cerebrospinal fluid, which may be mistaken at operation. The outlook is bad for patients with congestive failure or poor renal function, and very bad for those with both. In the majority, five to nine years later there has been improvement or no change in the state of the fundi, of the electrocardiogram, and of the renal function. The diastolic pressure is reduced in a good proportion, but this proportion grows less as the follow-up exceeds five years. Symptomatic relief is often striking and very satisfactory. A control series treated medically is hard to find, and has to be broken down into groups before any real comparison is possible. So far as comparison can be made at present, the mortality in Smithwick's series is noticeably lower than in those treated medically.

Dr. Horace Evans briefly reviewed hypertension from the days of Bright to the recent work of Trueta and his colleagues, and pleaded for more careful study of the types of hypertension. In selecting cases for sympathectomy, cardiac asthma is always a contraindication. A blood-urea above 100 mg. per 100 ml. is a contraindication in malignant hypertension but not in nephritis. The family history should not be neglected. Benign hypertension presents the greatest problem in selection, since patients with this condition often live happily for many years without operation. The majority of cases operated on show symptomatic improvement, especially relief of headache; and often great improvement in the condition of the fundi. We need more careful assessment and selection of cases, control series treated medically, biopsies of the kidney at operation, and a study of invalidism before and after operation; but sympathectomy, though only a palliative, certainly has a place in the treatment of hypertension.

Mr. D. W. C. Northfield gave his results in 46 cases operated on up to the end of 1947, and pleaded for discrimination in the use of sympathectomy. Dr. A. Rae Gilchrist reported fairly comparable series of cases treated medically and surgically in Edinburgh, which confirmed that surgery has its place, especially in malignant hypertension. Mr. F. E. Stock discussed sympathectomy in hypertension following toxæmia of pregnancy in young women, in which the operation has produced some of its best results. Dr. William Evans proposed a novel definition of hypertension which was designed to prevent unwarranted invalidism, but would certainly be a shock to doctors in insurance practice. His criteria for the selection of patients for operation included changes in the T wave in certain leads. Mr. A. Dickson Wright didn't care if the T wave was upside down or not, provided he could relieve a patient of a shocking headache and enable him to work and support his family. He favoured a transthoracic approach, which, he said, gives the surgeon a beautiful view, leaves the patient with nothing worse than a Horner's syndrome and a nice warm foot, and is apparently particularly acceptable to hypertensive high-pressure business men.

Modern Management of Megalocytic Anæmias

At the final meeting Sir Lionel Whitby began by reading a communication from Dr. George Minot, who was unhappily prevented by illness from being present. This told the story of pernicious anæmia down to the isolation by Rickes and his associates in America of a crystalline material in small red needles. This substance is said to be potent in pernicious anæmia in a single intramuscular dose of 3 microgrammes, and must surely be the active principle of liver extract at last. Omitting with characteristic modesty any mention of his own name, Minot concluded: "Despite the great advances in knowledge of pernicious anæmia that have occurred during my thirty-six years in medicine, there are puzzles enough to attract the curious for a long time to come."

Sir Lionel Whitby dealt ably with the principles of diagnosis and treatment. Macrocytosis, he said, is a symptom, just as anæmia is. It can be measured in various ways, but most satisfactorily by cell-volume determination, supplemented by the examination of a stained film. Sternal puncture is essential for distinguishing between the megaloblastic marrow of pernicious anæmia and the macronormoblastic marrow of the other macrocytic anæmias. Liver extract and folic acid are active when the marrow is megaloblastic, but folic acid has the disadvantage that it fails to prevent, and sometimes precipitates, neurological complications. Probably a complicated enzyme system is involved and its coördination is upset by too massive a dose of one constituent.

Dr. J. F. Wilkinson, having treated 1600 cases of pernicious anæmia in nineteen years, is frankly optimistic about the results, provided treatment is properly carried out. But liver extracts, like many other things, are not what they were before the war; and this is not surprising, since only liver rejected as unfit for ordinary human consumption goes to the pharmaceutists for the manufacture of a drug needed to cure a fatal disease. None of his patients treated with liver extract and hog-stomach preparations have developed neurological complications, but 15 of 20 patients treated with folic acid have done so.

Dr. C. C. Ungley described his experiences with the red crystalline substance isolated from liver in England by Lester Smith. This is probably, he said, the same substance as that found by Rickes in America Good hæmatological responses were produced by as little as 8 to 10 microgrammes, and the substance was as effective in subacute combined degeneration as liver extract is.

Dr. R. R. Bomford discussed errors in diagnosis and management which may result from confusion between pernicious anæmia and anæmia in hypothyroidism. These, he said, still occur, not perhaps in the great temples of hæmatology, where some of his audience had their dwelling, but in the outer courts and out-patient departments, where general medicine is still practised.

SURGERY

President: Mr. Vernon Pennell

Treatment of Tuberculous Lymphadenitis

Speaking on tuberculous cervical glands in children, Mr. Denis Browne stressed the importance of the tonsils and adenoids as a portal of infection, and called for further work on tuberculous infection of the adenoids, which he had found 3 times in a series of 15 adenoids sectioned. One of the difficulties in diagnosis was to detect mixed infection of cervical glands with tuberculosis and streptococci—grave infection by either organism was easily recognised. In treating tuberculous cervical glands he waited till the skin was becoming adherent, then made a $^1/_4$ inch incision, and, using the full strength of his fingers, expressed the swelling. He squeezed perhaps a dozen times until the squeezing yielded pure blood. Packing and drains were contra-indicated. The tonsils and adenoids must also be considered. Sea air and ultraviolet light were useful in misdiagnosed streptococcal infections. In his view splinting was ineffective and aspiration incapable of removing necrotic debris. Incision and curettage might fail to remove a necrosing gland and might open the jugular vein. Wide incision and wide excision of skin, leaving the wound to heal by granulation, left scars, which were only invisible a long way off. Block dissection though an excellent surgical exercise, would not eradicate the entire lymphatic system of that side of the neck and it carried a definite mortality, a big disadvantage where one was dealing with a disease which did not kill. The method Mr. Browne used did not spread infection.

Chronic Arthritis

Mr. W. GRANT WAUGH showed a short film on injection treatment with lactic acid, and the technique and results were discussed. It was agreed that the method has shown itself of use as an additional weapon in the attack on chronic arthritis, even though it is hard to separate the benefits of the treatment as such from those of the energetic physiotherapy which accompanies it.

DERMATOLOGY

President : Dr. C. H. WHITTLE

Occupational Dermatoses

Dr. J. T. INGRAM emphasised that investigation of the occupational dermatoses requires not merely study of a group of eruptions but comprehensive inquiry concerning the patient, his activities, and his environment. Occupational factors included not only the physical and chemical nature of the materials with which the patient came into contact, but also prophylactic and cleansing procedures, and atmospheric and other physical characters of the environment in which he worked, and the social, psychological, and economic aspects of his position. Dr. Ingram classified occupational dermatoses into three groups :

1. Those peculiar to particular trades or processes, and ranging from oil acne to anthrax, and from pitch warts to erysipeloid.
2. Traumatic dermatoses, caused by irritants which would damage the skin of any normal subject.
3. Those essentially constitutional, precipitated by wear and tear of the skin or by the development of personal sensitiveness.

Dr. Ingram stressed the importance, in diagnosis, of the patch-test, and, in treatment, of obtaining the patient's collaboration by explaining to him the nature of his disease.

Dr. SIBYL HORNER said that for prevention it was important to attend to inspection, selection, and cleanliness, and also the enforcement of minimal contact with irritants. She suggested that those who were to work with serious hazards should be introduced to them gradually by slowly increasing exposure to the irritant ; in this way susceptible persons could be weeded out before serious skin reactions appeared.

Dr. J. C. BELISARIO (Sydney) referred to dermatoses caused by mites, to slag-wool dermatitis, and to lesions associated with solar irritation. Dibutyl phthalate applied to the clothes had proved one of the best prophylactics against mites.

Dr. JAMES WARNOCK mentioned friction as a factor contributing to the development of dermatitis. In his opinion the increased incidence of occupational dermatoses in textile workers was due to inexperience among the personnel, longer hours of work, and changes of technique whereby more hazardous oils were used. In engineering much of the increased morbidity was due to the increase in high-speed work which necessitated the use of cutting oils. Examination had shown that of french-polishers 1 in 8, and of cloth scourers 1 in 3, had dermatitis but continued at work.

Dr. G. A. HODGSON said that of patients with dermatitis due to oil, 48% developed the eruption within two years of commencing the work. Dermatitis due to abrasives, as seen in coalminers, developed, in 82% of cases, after as much as 20 years at the work ; while dermatitis due to soap and cleansing agents also appeared after some 20 years.

Dr. W. J. O'DONOVAN recalled that work was the curse of Adam ; therefore anything unfortunate which occurs during working life must be due to this curse. Moreover, if work was a curse, leisure must be the right pursuit for man. Eruptions arising from psychological causes were thus often attributed by the worker to his occupation ; but the physician had to keep an open mind. Men, he observed, suffered from dermatitis; women with the same eruptions had eczema. Mother-fixation was often the cause of eruptions on the hands of young women, affording an excuse to return to the shelter of the maternal home.

Dr. A. THELWALL JONES discussing prevention, said that correct design of plant, education of the worker, avoidance of overcrowding, and proper facilities for personal hygiene were all important. Though not a dermatologist, he warmly advocated the provision of many more beds for dermatological departments.

Dr. R. M. B. MACKENNA said that in reablement there were two sets of problems, depending on whether one was dealing with early or long-standing cases. He discussed briefly "hardening" and the problems presented by "green labour," the necessity for rapid assessment and diagnosis, change of occupation, and the importance of keeping early cases at suitable work under supervision. Finally he described the problems of a rehabilitation centre for chronic cases.

Dr. ROBERT FORBES said that in arbitration or other court proceedings the doctor had to preserve an unbiased outlook. His attitude and conclusions in the early stages of discussion and report were of great importance ; and no statement should be made which might have to be retracted later.

NUTRITION

President : Prof. R. A. MCCANCE, F.R.S.

Importance of Proteins

Dr. D. P. CUTHBERTSON began by demonstrating that although protein consumption varies widely among different races and even among individuals in the same race, the proportion of calories derived from the protein of the diet is remarkably constant. In infancy, with its rapid growth, the figure averages 13·5% ; in adolescence it is still of the same order—11·9%. It seems to be largely independent of protein intake, for it is fairly constant among all social classes, and even under famine conditions it does not drop much below 11%. Before the days of rationing, the social class of an individual provided a good index of protein consumption. Today protein tends to form some 11–12% of the diet of all adults and from 13–14% of that of children. Requirements are increased during the latter half of pregnancy and during lactation. Protein loss after trauma and operations can be remedied by giving the patient as early as possible a diet rich in protein, to restore the negative nitrogen balance ; and if operations must be done on debilitated patients they should receive a preoperative diet rich in protein. One of the richest protein foods for this purpose is milk in which skim-milk powder is dissolved. Dr. Cuthbertson made the interesting observation that the protein-sparing action of carbohydrate is greater if the carbohydrate is consumed at the same time as the protein and not as a separate meal. Civilised man unconsciously recognises this by eating a carbohydrate dessert after a meat course.

Miss HARRIETTE CHICK, D.SC., explained that whereas some protein foods eaten alone will not produce optimum growth they will do so in combination. Thus beef-tea, which is now considered to have very little nutritive value, will not support the growth of young rats, but it will do so if supplemented with white flour. The combined effect of beef-tea and flour is greater than that of either alone. These observations suggest that beef-tea might be of some value to invalids if given with other foodstuffs, even white bread. Similarly potato protein will not support optimum growth, but whole potato fed to rats produces a rapid increase in growth. Dr. Chick suggested that since a mixture of proteins from barley, wheat, and soya-bean produces almost as good growth in rats as milk proteins, such mixtures might be used for feeding the undernourished infants operation for a purely inflammatory process. A transverse ridge, the intermittent protrusion of Falconer or concealed disc of Dandy, may not be shown to be pathogenic until the spine is hyperextended on the table. In spondylolisthesis root symptoms are often due to prolapse of the disc *above* the level of vertebral displacement, occasionally to prolapse below, but never (in Professor Dott's experience) to prolapse at the same space.

Just because the prolapsed disc is the cause of at least 90% of sciatica and lumbago-sciatica, it is particularly necessary to search for the oddities in the clinical picture, such as a suspicious umbilical nodule or an abnormally high C.S.F. protein, which may point to the radiculitis, extradural granuloma, tuberculosis of disc, or tumour, which may actually be present. The level of prolapse is usually clear from the root picture alone, but, since an obvious lesion at the expected site at operation may overshadow a second protrusion at another space, there may be a case for routine myelography.

In treatment, because manipulation is potentially dangerous and because of the inconstancy of any relief from manipulation or epidural injection, the issue lies between rest and operation; but the rest must be real rest and not just pottering about. On the whole, Professor Dott's bias lies towards operation, for since there is no evidence that rest, even in plaster, is really effective it is so much time deducted from the patient's life. If a month's rest gives no real relief, there is no point in delaying operation further, and the waiting period should be even less for those of neurotic temperament; in severe cases immediate operation can be guaranteed to relieve the pain. After operation, patients do early exercises, are up at the tenth day, and are back to sedentary work at six weeks and to strenuous occupations by six months. In 900 operations there have only been 3 deaths, and 1 of these was due to heart-failure.

Mr. NORMAN CAPENER vigorously defended the conservative position in treatment. "Disc lesion," he said, is a loosely used phrase. The actual prolapse is a mere incident in a long degenerative process in only one part of the complex intervertebral articular system, and the explosive clinical onset upsets the physiological control of the whole spine. Immobilisation in a plaster jacket, with the re-establishment of this control by active exercises, gives very good long-term results, and also separates out those cases which, by their failure to improve, will clearly need eventual operation. The results of poorly judged operations are often appalling, and without careful serial radiography it is only too easy to misdiagnose a tuberculous spine.

With equal emphasis, Mr. R. H. YOUNG maintained the value of operative treatment, on the basis of experience with 791 laminectomies performed in association with Mr. B. H. Burns. He was prepared to be quite dogmatic in asserting that the ordinary patient with sciatica or recurrent low back pain can be taken to have a prolapsed disc unless radiography shows some other disorder. Clinical examination is of the simplest, and the picture is characterised by rigidity of the lumbar spine in attempted flexion, with freedom of side bending. The neurological features are quite useless in localisation, and indeed no localisation is possible before operation, when both the 4th and 5th discs must be inspected; double lesions are found in 12–20% of cases. It should not be thought, however, that Mr. Young advocated operation for all, or even for most, cases. The mild ones get better if left to potter about without any interference from the physiotherapist. Severe cases should be rested in bed for two or three weeks in the most comfortable position they can find, and operation should not be deferred too long if pain persists, since this makes for neurotic complications. A five-year follow-up showed that 83% of patients with lumbosacral lesions were symptom-free and back at their old job, compared with 73% of the patients with a prolapse of the 4th disc. But the cure-rate fell steeply for re-explorations, which was why all lesions must be found at the first intervention.

The general discussion which followed showed that operation versus conservatism remains a vexed question and one which may be decided for the individual by such a personal experience as that of Prof. T. P. MCMURRAY—a single attack of sciatica recovering spontaneously without recurrence.

Operative Treatment of Recent Fractures

Proceedings on the second day were on a less controversial level. Everyone agreed with Mr. BRYAN MCFARLAND's theses: that the fracture patient should be at least no worse off after treatment than if left alone; that he should be positively better treated than untreated; that operation should leave him in a better state than non-operative treatment; and that the added risk of operation—a real one—should be commensurate with the expected benefit. The terrible result of one badly performed or infected plating of a fractured femur far outweighs any number of good results. He divided fractures into those in which operation is essential, as for the olecranon with retraction; where it is permissible, as for a difficult fracture of the forearm bones; and where it is inadvisable, as for the scaphoid at the wrist. Mr. JAMES PATRICK, agreeing with these sentiments, pointed out that an obsession with X-ray appearances results in far too many operations. The most perfect X-ray reduction is no index whatever to the function of the part. Surgeons too often still use dissimilar metals for their plates and screws, with inevitable electrolysis and the risk of spontaneous fracture after many years.

Mr. CAPENER mentioned the relative but valuable indication for operation in the mobilisation of elderly patients with intertrochanteric fractures of the femur. Here the early insertion of a combined pin-plate makes all the difference to reablement.

Treatment of Acute Osteomyelitis

Dr. J. TRUETA said that even the experience of four years with adequate supplies of penicillin has not led to agreement on methods of treatment and on results in osteomyelitis, so that some authorities like Leveuf could even declare that there have been no changes of importance. Leaving aside the relatively benign condition in infants, the clinical picture in young children should have been completely changed by chemotherapy; but in fact, though the initial septicæmic phase can now be controlled, the effect on the bony focus is not always so satisfactory. Here there is a septic thrombosis of the nutrient artery, with pus elevating the periosteum, and massive death of bone can be prevented only by a rapid restoration of collateral circulation through the periosteal vessels. This requires that the periosteum be kept applied to the shaft, and that intraosseous tension and œdema be reduced so as to leave the vessels patent. To secure this, operation is essential, except in the earliest cases with complete dramatic response to penicillin and disappearance of local pain and tenderness. Delay of even 48 hours allows irreversible damage to take place; hence the importance of the general practitioner in referring to hospital at once any possible case of osteomyelitis. Operation means simple incision (not reflection) of periosteum where ballooned by pus, drilling of the bone to either limit of the diseased segment, and primary suture, followed by immobilisation. Penicillin should be continued for up to three weeks, and in large doses; for the concentration of the drug within the bone is often much lower than in the blood-stream. Only in this way will a radiographic return to normal accompany clinical subsidence and only thus can recurrent flares of infection be abolished.

Surgery of Congenital Heart Disease

Dr. **Maurice Campbell** analysed the possibilities and place of active therapy in three conditions—patent ductus arteriosus, coarctation of the aorta, and cyanotic heart disease. In the presence of the classical murmur and enlarged pulmonary trunk the diagnosis of patent ductus is not difficult, but the existence of cyanosis would contraindicate operation, for in such a case the ductus might be a valuable compensatory channel. Where there is an uncomplicated patent ductus surgical occlusion is a complete answer and should be considered wherever there are significant symptoms. The mortality is small, but with a symptomless patient it cannot be ignored. The results, however, are excellent and operation is best undertaken between the ages of 7 and 20.

Coarctation is more difficult to evaluate from the surgical standpoint. The operation is undoubtedly difficult and carries a definite risk, but it should be considered in patients under 20 years where there are severe symptoms or where the blood-pressure is unduly high. In older people the general condition is often very good and, even without operation, the chances of survival into middle or late life are much better. It should not be forgotten that the development of atheromatous changes in the aorta as years advance makes surgery more difficult and may preclude it completely. In the cyanotic group of heart lesions, however, there need be few qualms about advocating surgery, if it can be undertaken, since the prognosis is so bad and there is no alternative treatment. The basic lesion in all types consists of lack of blood-flow to the lungs, and this is usually produced by stenosis or obstruction in the region of the pulmonary trunk. The surgical remedy consists in an operation which provides an anastomosis or artificial ductus between a systemic and pulmonary arterial trunk. Fallot's tetralogy is the best known and most common form of cyanotic disease which has responded well to the Blalock-Taussig operation. The suitable case for surgery is a child who is cyanosed soon after birth and has a high red-cell count. Size and intelligence are usually normal, though the child is under weight. The main disability appears on exertion when even a short walk of 40–50 yards is as much as can be managed without distress. On clinical examination the heart is usually small and shows the classical "sabot" shape in only a third of the cases. The pulmonary shadows are diminished in size and pulsation. Diagnosis is often straightforward, but there are instances in which cardiac catheterisation and cardio-angiography are needed in order to establish the nature of the lesion. Deaths are inevitable with any form of surgery in this condition, and a mortality-rate of 16% is probably the lowest that can be achieved at present. The results in those who survive are, however, remarkably gratifying, and there seems to be little, if any, ill effect from the newly constituted ductus.

Mr. **Holmes Sellors** felt that all cases of acyanotic ductus should be regarded as potential candidates for surgery, though clearly extreme youth or old age or other factors might modify this outlook. The apparent lack of symptoms in many cases does not necessarily mean that the patient is suffering from no disability, and in nearly every instance a condition of cardiac invalidism is established as a result of knowing that an abnormal heart condition exists. The low mortality of the operation of ligature of the ductus and the excellent results that are obtained are most gratifying. Recanalisation of the channel, which is said to occur fairly often, is probably not as great a danger as has been suggested though fear of its occurrence has led some surgeons to divide the ductus and oversew the cut ends.

Coarctation is not always a simple lesion, and associated cardiac lesions are not unknown. Crafoord's operation, in which the stricture is excised and a junction made between the cut ends of the aorta, is the procedure of choice, but may have to be modified if unexpected disproportions in the region of the stenosis are found. The general fitness of many young patients with this condition is often remarkable, and it is felt that surgery should only be undertaken when the symptoms are severe.

In pulmonary stenosis the form of operation has not been finally settled though the results of the Blalock procedure have been satisfactory. In Pott's operation a small anastomosis with a lumen of 4-mm. diameter is constructed between the left pulmonary artery and the aorta just below the arch, and good results have been recorded. More recently, if the stenosis has been shown to lie at the pulmonary valve deliberate division of this structure has been successful.

Mr. **Brock** described his experiences in cyanotic heart conditions and emphasised the urgency of their relief in children. The disability is often so severe as to make life barely tolerable, but a successful operation leads to dramatic recovery. The risks of surgery are certainly worth taking.

Dr. **A. Rae Gilchrist** has observed over 100 cases of patent ductus and considers that the lesion is usually an isolated one and amenable to treatment. Early recognition is important, and operation can be considered at the age of 7. In the cyanotic group the difficulties of operation are considerable, but good results in his own patients have been achieved by Pott's operation.

Upper Respiratory Disease and the Lung

Infection of the paranasal sinuses, Dr. **W. Paton Philip** said, often results in atelectasis of a lobe or segment of a lobe, most commonly the right and left lower lobes, and right middle lobe. The atelectasis is often transient, but recurs unless the sinus infection is successfully treated. Among an average of 2375 new cases referred to an outpatient chest clinic each year, approximately 372 cases of sinus infection with atelectasis were found: these patients were referred because of a history of cough, rise of temperature, or (most frequently) recurrent attacks of "pneumonia." In treating the sinus infection, Dr. Philip has found short-wave diathermy of the greatest value, though in many cases antrum puncture and Caldwell-Luc procedures are necessary. Prolonged and energetic treatment is essential for if the condition goes unrelieved, it may progress to frank bronchiectasis.

Dr. **Trail** agreed that there is a strong correlation between sinus infection and bronchiectasis, but was doubtful as to which comes first. In bronchiectasis he said, it is always the *two lower lobes, the right middle* lobe, or the lingula that are involved—never the upper lobes unless these have been affected by a previous lung abscess. Experimentally, vitamin deficiency during pregnancy causes maldevelopment of the finer bronchioles and this finding deserves further attention. Dr. **F. H Young** made three points:

> (1) In a recent case, an X-ray film of the sinuses was taken immediately after a bronchogram, and this showed iodised oil in the antrum. There is therefore no doubt that infection in the lung can be transferred to the sinuses, and probably in most cases there is a vicious circle of sinus-lung-sinus infection.
>
> (2) Removal of tonsils and adenoids before the age of 4 may predispose to sinus infection.
>
> (3) Can it be assumed that, if the antra are clear, the other sinuses are also uninfected ?

Dr. **Philip** thought that when the antra are shown to be clear it is probably unnecessary to exclude infection in the other sinuses.

Treatment of Pneumonia

Dr. **Lindsey Batten** wondered whether lobar pneumonia has changed its character during the last thirty years; his own impression is that it was already becoming milder before the advent of chemotherapy. At and children of Central Europe, where the daily milk ration is barely $2\frac{1}{2}$ oz.

The most interesting and certainly the most provocative paper of the meeting—*Investigations in Germany on Wheat Flour of Various Extractions as a Source of Protein for Growing Children*—was read by Miss E. M. WIDDOWSON, PH.D., who described her experiments on 150 children of a Duisberg orphanage fed on different kinds of bread. The children, who were divided into five similar groups, had the ordinary German rations, except cereals, and in addition as much of the bread under test as they liked. Each group received bread made from flour of different extraction, some of the bread being enriched with B vitamins and iron.

The flours were (1) 100% extraction; (2) 85% extraction; (3) 70% extraction; (4) 70% extraction, enriched with as much vitamin B_1, riboflavine, nicotinic acid, and iron as is present in 100% extraction flour; and (5) 70% extraction enriched with the B vitamins and iron present in flour of 85% extraction. The diet was also supplemented with calcium carbonate and vitamins A, D, and C in sufficient amounts. At the beginning of the test all the children were under weight and under height. Before the test the children were examined clinically; their hæmoglobin and hæmatocrit values were determined, their bones and gastro-intestinal tract were radiographed, and records were made of their height, weight, and dental condition. The amount of bread consumed varied considerably, but averaged 800 grammes daily, this amount providing 2000 calories. The bread formed the bulk of the protein consumed, only 7–8 grammes of protein a day being derived from animal sources.

At the end of a year no difference was found in the health and general condition of the five different groups of children. Dr. Widdowson was careful to point out that this experiment does *not* prove that white bread is as good as brown for children; but unfortunately some newspapers ignored her statement that this was proved true only under the particular conditions of this experiment and not under all conditions. She afterwards showed five of the German children who participated in the test.

Dr. L. E. GLYNN, speaking on Protein Deficiency and Liver Disease, outlined the results of experimental protein deficiency in animals. These are increased susceptibility of the liver to chemical poisons, such as chloroform and carbon tetrachloride; gross fatty infiltration of the liver, leading to cirrhosis if the deficiency is continued long enough; and massive necrosis of the liver if the protein deficiency is accompanied by vitamin-E deficiency. Dr. Glynn discussed the part played by the sulphur-containing amino-acids, methionine and cystine, in protecting the liver against chemical damage and fatty infiltration.

Other Subjects

Professor SANTOS (Portugal) read a paper on Disturbances of Metabolism and the Neuro-endocrine System after Psychic Trauma during the Second World War.

A film on agenised flour and canine hysteria was shown by Sir EDWARD MELLANBY, F.R.S. This was followed by a film, produced by the staff of the Rowett Institute, on lambing in relation to the feeding of the pregnant ewe. This demonstrated very clearly that when ewes are given a diet low in protein the result is an increase in stillbirths and neonatal mortality. Dr. GILLMAN (Johannesburg) said that he had made similar observations on maternal diet and the newborn among the native population of South Africa.

The recent purification of the anti-pernicious-anæmia factor (vitamin B_{12}) by Lester Smith was explained in detail, and the results of clinical trials with it were graphically demonstrated by Dr. C. C. UNGLEY. Other exhibits illustrated the effect of diet on resistance to tuberculous infection (Dr. S. R. SENGUPTA), blindness in cattle resulting from vitamin-A deficiency (Mr. T. MOORE, D.SC., and colleagues), the results of combined deficiency of vitamin E and protein in rats (Dr. MOORE), and the effect of chronic partial vitamin-C deficiency on muscles and joints in guineapigs (Dr. E. KODICEK and Mr. P. D. F. MURRAY, D.SC.).

DISEASES OF THE CHEST

President: Dr. R. R. TRAIL

Bronchial Carcinoma

The main emphasis here was on avoidance of delay in establishing the diagnosis. The high incidence of bronchial carcinoma, and the realisation that early cases can be successfully treated, should make the profession more alive to the possibility of its presence.

Mr. R. C. BROCK pointed out that the early symptoms may easily be overlooked or attributed to more innocent conditions. Cough, the earliest and most prominent symptom, is often put down to smoking or influenza. Hæmoptysis, pain, and signs of infection are other early features. In any suspected case radiography is essential, and bronchoscopy may confirm the diagnosis. The one form of treatment that has proved its worth is radical surgical excision, but unfortunately only a small proportion of sufferers are suitable for surgery. Mainly through earlier recognition, an original operability-rate of 8% has lately increased to 11% in 666 cases and reached 21% in the last year. Of 96 patients on whom excision was practised 78 survived, and of these 50 are still living. The type of operation is one in which the hilar structures are secured individually and the lung and glands removed. Recent developments, such as dividing the vessels intrapericardially, have extended the scope, and a more complete clearance of the mediastinal tissues, in the form of a block-dissection-pneumonectomy, has obvious possibilities.

Mr. G. A. MASON provided figures from an experience of 1000 cases. Of these 353 were explored operatively and 202 were found suitable for excision, giving an operability-rate of 20%. Analysis of early symptoms shows that cough and pain are the most common initial features, followed by dyspnœa, lassitude, and hæmoptysis. The delay between early symptoms and diagnosis is assessed at over eight months, and of this delay the medical profession can be held responsible for at least half.

The prominence given to surgery as the only form of treatment was balanced by Dr. E. L. G. HILTON's remarks on radiotherapy. It is popularly held that a patient excluded from surgery should be referred for deep X-ray therapy, but many patients recommended for this form of treatment are quite unsuitable. There must be careful selection, and out of 360 patients seen in the past seven years only 213 were accepted for therapy. Also therapy can be divided into palliative and radical forms, so that strictly only patients accepted for radical treatment (89 in this series) should be included in assessing the value of radiotherapy. Of those radically treated, some return to work and survive for an appreciable period in comfort. Problems of dosage in the depths of the chest and the inadvisability of using therapy in the presence of sepsis have to be considered, but patients should not be made ill by treatment, and after two or three weeks they show a steady increase in weight and general improvement.

Dr. TRAIL mentioned the periodic character of the cough in the early stages and how there is often a steady decrease in the intervals between coughing bouts. Mr. RONALD EDWARDS pointed out that the incidence of bronchial cancer is higher than that of gastric cancer, and only just below that of mammary growths. Dr. F. H. YOUNG said that pneumonectomy is not followed by gross disability, and physicians need not worry about the effects. Important though radiography may be in diagnosis, the first positive evidence of malignancy may come from bronchoscopy.

SCIENTIFIC INFORMATION

THE ROYAL SOCIETY'S CONFERENCE

In 1946 the Royal Society held an Empire Scientific Conference in London, and about the same time a British Commonwealth Scientific Official Conference was convened to consider the best means of ensuring collaboration between civil government scientific organisations of the Commonwealth. These two conferences thought that certain aspects of this subject needed more detailed examination, and the Royal Society therefore resolved to call another conference to which representatives of the Dominions and Colonies, and observers from the United States, should be invited, and at which the interests of scientists as users of scientific information should be especially considered, and the question of abstracting services examined.

This second conference was held in London from June 21 to July 2; but much-work had previously been done by the Royal Society's officers and by steering committees: no fewer than 46 papers, some very long, had been circulated before the opening day.

The plan of the conference was, briefly, that there should be four main sections, that each section should hold two plenary sessions, and that detailed work should be done by working parties within each section. At the first plenary session the agenda already drawn up for the working parties was approved or modified, and the composition of the working parties decided; at the second plenary session the recommendations of the working parties were reviewed and approved. The four sections were concerned with (1) publication and distribution of papers reporting original work; (2) abstracting services; (3) indexing and other library services; and (4) reviews, annual reports, &c. A session of the full conference to approve the final form of the recommendations for submission to the council of the Royal Society was held on the last day, and a closing session at the very end.

In welcoming the delegates, Sir Robert Robinson, P.R.S., explained that the conference was concerned with the sciences, but not with social science or the "so-called humanities." But he protested against the term "humanities" when, as so often, it is used to represent something to which science cannot attain. He made the point that science is concerned with human welfare and with spiritual values. Speaking of publication, he recalled Faraday's opinion that the research-worker should do three things: begin his research, end it, and publish it. At present the amount of money spent on publication of results of scientific inquiry was less than 1% (more probably $^1/_8$ to $^1/_2$%) of the amount spent on the research itself. This could well be increased, since publication is so essential and important a part of the spread of scientific knowledge.

After Dr. E. Marsden, of New Zealand, had emphasised the importance of speed in the spread of scientific information, in relation to economic development, Sir Edward Appleton, F.R.S., made a vigorous appeal for some system by which scientists could receive the information they want, sifted from the enormous mass of literature now produced. A man doing nothing but read current papers on fundamental science for 8 hours each day would be 10 years behind after the first year of work, yet "scientists live chiefly on the printed word." The scientist must get what he wants quickly and in the right form, and for Sir Edward this means reprints of the relevant original papers, and prompt short abstracts of related subjects. The whole subject of scientific literature is of the very greatest importance.

Sir Henry Tizard, F.R.S., put forward another point of view—that of the scientists rather isolated from the main centres of investigation either in Britain or the Dominions, and especially, perhaps, in the Colonies. The great need is to get what is already known across to those who need it but who cannot have that easy access to literature or to other scientists which is a feature of the big institutions.

BACKGROUND INFORMATION

One feature of great interest in this conference was the use of questionaries, two of which had been circulated several weeks previously, to various individual scientists and organisations. These questionaries had been carefully compiled. One, addressed to individual scientists, was designed by Prof. J. D. Bernal, F.R.S., "to find out in as much detail as is practical the habits of scientific workers in 'searching the literature'." Many questions were asked, and opinions, as well as statements of reading habits, were invited. The analysis of the results comprises some 30 pages of the paper issued on the subject, and required a great effort by a large number of people. The questionary was distributed to 8 scientists working for the Medical Research Council, and to 200 scientists engaged in non-medical work; the evidence indicates that in assiduity of reading the Medical Research Council led the field by several lengths, with 20·4 papers looked at, per person per week, against 10·5 for the (Cambridge) runners-up, and with 7·4 studied, against 4·8 at Cambridge. Rothamsted, the Department of Scientific and Industrial Research, and industrial scientists (to continue the metaphor) also ran. Between 82% and 100% of the scientists who answered the questionary used abstracts in the course of their scientific work. As Professor Bernal remarked in introducing his report on this interesting piece of operational research, the general trend of the replies indicated the need for more reviews, more reprints, and better library services.

The questionary addressed by Sir David Chadwick to various abstracting agencies sought information on organisation and technique, but also contained questions relating to the needs of users of abstracts and the quality and scope of abstracts provided for them. The replies indicated substantial differences in content and method. Some abstracting organisations aim to cover all papers in their fields, usually providing short objective abstracts whose purpose is chiefly to help readers to decide which original papers they should read. Other organisations adopt a selective method, abstracting only the more important papers on their subjects, and usually providing abstracts containing more detail than those of the first group. The needs of the readers of the abstracts issued in the various fields of science should, and indeed usually do, determine the types of abstracts provided. Certain abstracting agencies of long standing collaborate to produce abstracts of common interest; for instance, besides producing their own separate publications, the Commonwealth Mycological Institute and the Bureau of Hygiene and Tropical Diseases jointly produce the *Annotated Bibliography of Medical Mycology*. Some abstracting agencies provide information services in addition to their published matter. Some are sponsored and supported by Commonwealth governments; others are attached to societies.

PUBLICATION AND DISTRIBUTION

Professor Bernal drew attention to the plethora of material published and the confusion as to distribution which the present system entails. He wished, like Sir Edward Appleton, to obtain for the scientist the maximum of relevant information in the minimum of time and at the minimum cost. His proposals have unfortunately been misunderstood by some people outside the conference: he would continue to make use of existing agencies—societies, editors, and referees—but lays emphasis on the desirability of publishing papers that time the problem was not to cure a self-limited disease but to sustain the patient's resistance until he recovered. The length of the illness was all-important, and exhaustion the danger most feared. Rest, nourishment, and economy of exertion were first objectives, and expert nursing in hospital the obvious means. Chemotherapy, by greatly shortening the course of fever and toxæmia, has largely eliminated the danger of exhaustion in those not handicapped by age or serious incidental disability. Endurance, as a rule, is scarcely in doubt, and the means to secure it thus lose their dominating importance. Home, not hospital, may be the place of choice, and the management of pneumonia at home thus assumes a new importance. Many details of management, however, are still open to discussion—e.g., the temperature of the room and relative importance of ventilation and warmth; the allocation of priority among sleep, food, and drugs; hot, tepid, or cold water for sponging; the patient's position in bed; the choice and dosage of drugs for relief of pain and cough, for sleep, and as aperients; the usefulness or futility of poultices; the place of oxygen and of cardiac or respiratory stimulants in treatment. Chemotherapy is not yet, and is perhaps not to be, standardised. No close agreement appears between recent authorities on the choice or dosage of sulphonamides; the precise place of penicillin, and even the method of administration, have probably still to be determined. The considerable minority of pneumonias, benign or virulent, which are untouched by chemotherapy, must not be forgotten. Apart from trial and error their recognition depends largely on the help of the pathologists, who may give warning of dangers not otherwise to be foreseen and can greatly increase the possibilities of intelligent therapeutic tactics.

Dr. Young also thought that pneumonia was becoming less virulent before the introduction of sulphonamides—judging by the decreased number of cases visited in consultant practice. Dr. Trail said that rusty sputum is less commonly seen nowadays, though the pneumococcus is still the causal agent in the vast majority of cases. Dr. Batten attributed this to cure of the pneumonia before any sputum, rusty or otherwise, is produced.

OTORHINOLARYNGOLOGY

President: Mr. V. E. Negus

The Sphenoidal Sinus

The sphenoidal sinus is out of sight and out of mind. But only a thin sheet of bone separates it from very important structures, and where there are dehiscences the mucosa may actually evaginate and come into direct contact with these structures. Thus the symptoms of infection may be very varied. Air exchange inside the sinus is slow and evaporation slight, and the glands of its mucosa are therefore sparse. But the mucous membrane around the ostium on the nasal side is thick and readily swells; which means that blockage of the opening can usually be overcome by shrinkage there. Recalling these facts, Dr. Arthur W. Proetz (St. Louis, U.S.A.) said that the changes in sinus mucous membranes caused by infection and allergy are more fully reversible than was thought, and cilia will persist even on a very chronically infected and thickened mucosa. In treating sinuses great care must be taken to preserve the natural action of the cilia, avoiding destruction of mucous membrane, especially at the ostium. Sphenoiditis on the whole is of low grade; hyperplasia is restricted and irreversible changes are rare. In treatment the congestion should be reduced by displacement therapy, using $^{1}/_{4}$% ephedrine and continuing for ten days; antiseptics added to the fluid are probably of no value. Fulminant cases (which are rare) require chemotherapy, and surgery may be necessary both in these and in chronic cases not reacting to conservative measures. Dr. Proetz believes in making a narrow vertical oblong opening through the inner part of the anterior wall, well medial to the ostium and leaving it untouched. The middle turbinate is usually left in situ, but he does not object to removal of part of it if it is found to obstruct the surgeon's view.

Mr. F. C. W. Capps, who fully agreed about the need for a conservative attitude, said that, while acute sphenoiditis is rare, chronic infection is commoner; and here the treatment of the associated posterior ethmoiditis usually suffices. Operating in acute cases he enlarges the natural opening downwards, but often a partial middle turbinectomy is advisable. Less severe cases can be treated by washing out the sphenoid via the normal ostium. In his opinion retrobulbar neuritis is seldom improved by operating on the sphenoid. Dr. T. C. Graves stressed the relationship between sphenoidal sinus infection and mental disease; but Mr. J. C. Hogg has found the treatment of sphenoidal sinusitis disappointing in mental cases. Aspiration of the sinus, he said, is often essential to confirm the diagnosis.

At the end of the discussion Mr. Capps said he was glad to feel that there was general agreement as to treatment. He summed it up as: for acute cases, chemotherapy, and drainage from the sphenoidal sinus by suction or by enlarging the normal ostium; for chronic cases, conservative measures such as displacement therapy, followed (if they fail) by operation as described by Proetz.

Poliomyelitis and Tonsillectomy

Dr. A. M. McFarlan told how, 9–14 days after tonsillectomy, five children in one family developed bulbar paralysis of which three died. The operation apparently converted a symptomless poliomyelitis infection into a highly fatal form of the disease. Of cases of poliomyelitis developing within 30 days of tonsillectomy an unusually high proportion are bulbar, and in monkeys introduction of poliomyelitis virus by the tonsils often leads to bulbar paralysis. Histological studies have shown that in man the pharynx is a favourable portal of entry for the poliomyelitis virus, and these findings are in accordance with the idea that there may be a causal relation between tonsillectomy and bulbar poliomyelitis. In Dr. McFarlan's opinion there is very little evidence that recent tonsillectomy renders children more liable to infantile paralysis, but it seems to increase the risk of the disease being of the bulbar type. The risk is greatest during epidemics, when the virus is spread widely through the population, and at such times postponement of tonsillectomy can be expected to eliminate some cases of bulbar paralysis.

Dr. J. Alison Glover felt that the risks of tonsillectomy are definitely increased during an epidemic of poliomyelitis and that they outweigh the harm likely to be done by postponing operation. Mr. G. Bateman said that there is no unanimity among ear, nose, and throat surgeons in the United States on this subject. He thought that there probably is some increased risk of the bulbar type arising, but there are also disadvantages in postponing the tonsil and adenoid operation, including prolongation of general malaise and the danger of complications. He suggested the use of isolation cubicles. Mr. Negus pointed out that statistics will show the increased risk of poliomyelitis, but not the various troubles caused by not doing the operation. Major-General E. A. Noyes (U.S.A.) stated that the policy of the United States Army has been to stop tonsil and adenoid operations during epidemics of poliomyelitis.

In answer to Mr. Hogg, Dr. McFarlan said there is no evidence that dental or other operations increase the risk. He was strongly in favour of cubicles for ear, nose, and throat cases.

(*To be concluded*)

refinement, or extension of present-day methods of spreading information. Subjects which needed consideration were discussed at some length, and recommendations were made to which the attention of the Royal Society was invited. As the arguments were stated and restated it became evident to some, if not to all, delegates that the sciences represented are so different that procedures suitable to one are by no means always suitable to another. This fact was responsible for some confusion of thought and much vigorous argument, and one of the valuable results of the conference was that the particular needs of many branches of science were stated. When the recommendations are published in their final form, readers will be able to see how far they can be applied to medicine.

In winding up the conference at the final session, Sir **ROBERT ROBINSON** referred to the resolution that the Royal Society be invited to set up a standing committee on scientific information services to implement the recommendations made, and added the rider that funds would be needed for this purpose, and that they must presumably come from national sources Mr. **SAUNDERSON**, on behalf of the Dominions, complimented the Royal Society on the efficiency with which the conference had been conducted, and Mr. D. W. **BRONK** (representing the U.S. National Academy of Sciences) spoke of the need for internationalism in science and in scientific journals. Tributes were paid to Professor Bernal and the editors of the other sections, whose interest was inspired solely by the desire to advance the cause of science.

MEDICAL PRACTICES COMMITTEES

THE Minister of Health has appointed the following as members of the Medical Practices Committee, constituted under the National Health Service Act:

Dr. W. E. **DORNAN** (Sheffield), chairman; Dr. J. A. **PRIDHAM** (Weymouth); Dr. **ANNIS GILLIE** (London); Dr. J. F. **MURPHY** (London); Dr. D. T. **MACDONALD** (Belford, Northumberland); Dr. D. B. **EVANS** (Wrexham); Dr. P. V. **ANDERSON** (Shildon, Co. Durham); Mr. **HENRY LESSER**, chairman of London executive council; and Mr. R. **WILBERFORCE** (London), barrister-at-law.

The committee's functions include the consideration of applications by general practitioners to join the National Health Service in England and Wales, and to decide whether further doctors are needed in the public service in the area to which the application refers. They will also, on request, advise doctors whether transactions into which they propose to enter comply with the provisions of the Act prohibiting the sale of goodwill. The committee's offices will be at Devonshire House, Mayfair Place, Piccadilly, London, W.1.

SCOTLAND

The Secretary of State for Scotland has set up, under the National Health Service (Scotland) Act, a similar committee with the following members:

Dr. A. F. **WILKIE MILLAR** (Edinburgh), chairman; Dr. I. D. **GRANT** (Glasgow); Dr. W. **JOPE** (High Blantyre, Lanarkshire); Dr. J. R. **ANDERSON** (Fortrose); Sir **WILLIAM MARSHALL**, chairman of Lanarkshire executive council; and Mr. H. A. **SHEWAN** (Edinburgh), advocate.

The committee's offices are at 12, Carlton Terrace, Edinburgh, 7.

Disabilities

8. PULMONARY TUBERCULOSIS

ANY serious long-continued illness such as pulmonary tuberculosis is bound to impose some modification of outlook and of behaviour on even the least impressionable of patients. In the early stages of the disease the consciousness of the fact that one is "T.B." pervades almost every waking thought and imbues the outlook with anxiety or actual fear. In retrospect, I can well remember what an intensive process of adjustment I had to undergo when I was told I was suffering from pulmonary tuberculosis. Career, job, financial prospects, social relationships, and a goodly measure of happiness seemed closely bound up with physical well-being; and all were being plunged into the melting-pot at a time when I was far from being at my best either physically or mentally and when my knowledge of the true facts regarding my health was fragmentary and even distorted.

The tendency at this time is for the patient to speculate endlessly on every possible aspect of his illness. Will he get better? How long will it take? Will he become a chronic invalid dependent on others? How long will his salary continue? Will he lose his job? What will other people think? Has he already infected other members of his family? What will happen to them now and in the future, &c., &c.? In short, he is at this time in need of as much material reassurance as he can get—not the "Don't worry, everything is going to be all right" type of thing but good solid reassurance on specific points such as: "Your salary will continue as before," or "The tuberculosis allowance will be so much a week, supplemented by so much towards rent and other expenses," or "Peter and Marjorie were X-rayed yesterday and they are all right."

Even if the outlook is less satisfactory the patient will derive some satisfaction from knowing the worst *provided he feels confident that whatever possible is being done to remedy matters.* He himself will be glad to escape the actual responsibility of settling family, business, and social affairs. The impulse towards escapism is, indeed, distinctly strong in the early stages and some temporary retreat from reality is not a bad thing; personally I shall always be grateful to the author of a long, rambling, and entrancing novel which swept me off to another world for hours at a time when the real world was grey and full of menace.

In the early stages of his illness, therefore, I should say the tuberculous patient requires three things to tide him over his psychological crisis:

(1) Material reassurance on specific points which are causing him anxiety and concern.

(2) Helpful advice regarding his many problems from someone (preferably his physician) on whom he feels he can rely.

(3) Some harmless avenue of escape to divert his attention from his various troubles, both immediate and prospective.

When, this first, somewhat intensive, phase of adjustment is over, there ensues a period of chronic dissatisfaction. Recovery is still a long way off and apt to recede even further with little or no warning; problems have had time to harden and the patient time to appreciate his own incapacity to solve them while he remains an invalid; the unpleasant effects of tuberculous toxæmia may still be present, and positive signs of advancement in health are distressingly slow in appearing; the sense of being "cut off" and "out of things" persists uncomfortably and the predominant inclination is still to get back as quickly as possible not only to normal life but to the pristine stage of full activity.

* * *

As time goes on the patient becomes more at ease with his environment and somewhat less impatient with his enforced limitations. Gradually his attention becomes caught up with smaller, more immediate interests. When bigger and more unpleasant issues loom up, and depression threatens to close in, a new departure along some hitherto unexplored path often helps to keep interest fresh and alive. Writing instead of reading, doing something with the hands such as toy-making, rug-making, or even jig-saw puzzles, all help to provide concentration on the immediate and practical to the exclusion of greater but more remote problems. At this separately so that the worker may receive what he wants and no more.

The conclusions and recommendations of the section were extensive. They related partly to an educational campaign, which should be undertaken by all learned societies, to improve the standard of scientific papers. The aim should be to produce the best papers as quickly and in as short a form as possible, and at the lowest effective price; but the emphasis should be on quality. The working parties made practical suggestions on these points. They also made recommendations relating to the issue of short versions of papers when the full versions are too long to interest more than a few persons; in such cases the complete experimental details could be deposited in some stated place, to be consulted or copied on request, but not to be printed. Consultations between editorial boards of journals having similar interests were advocated, and better reprint and library services, with attention to the need for making papers more rapidly available than they are at present to readers in the Commonwealth. More controversial was the suggested *production of fairly full précis by the authors of original* papers, which might be published separately in "federated précis journals"; but the distinction between these and informative abstracts was admittedly indefinite. Opinion on this suggestion was divided; many delegates could not see much practical value in the proposal, which was adopted on a bare majority vote only.

ABSTRACTING SERVICES

Sir David Chadwick, for many years secretary of the Imperial (now Commonwealth) Agricultural Bureaux, said that abstracts should serve the needs of scientists, and the readers should constantly be kept in mind. *Abstracts are not bibliographies, and numbers are not so important as quality, accuracy, and general cover.* Abstracters must be in close touch with those they serve, and should cast the abstracts in a form which fits the needs of the particular readers for whom they cater. There is some overlap between different existing abstracting services, but this is not an important matter.

Sir Alfred Egerton, SEC.R.S., commented on the importance of good indexes in abstracting journals.

The point of view of agricultural workers in the tropics was put by Mr. B. A. Keen, F.R.S., who said that their very diverse needs are well served by the Commonwealth Agricultural Bureaux. They include on the one hand scientists who require abstracts of information on abstruse chemical and physical subjects, and on the other hand non-specialist officers whose work is in the field, remote from libraries, but who must keep in touch with the broad trends of research so that they may apply modern knowledge to their everyday problems. These field workers have neither opportunity nor time to look through a flood of literature; they need periodical reviews, which could perhaps be produced by the bureaux, but organised by some institution half-way between themselves and the bureaux which could also maintain a flow of information in the reverse direction, keeping the bureaux informed of the activities and problems of the field workers.

Mr. J. E. Cummins, representing Australian scientists, suggested that the preparation of abstracts of important papers must eventually be a responsibility of the authors of the original papers. Authors should provide their own abstracts, and these should be sent by the editors of the journals concerned to such organisations as their subjects indicate to be published in abstracting journals. Dr. C. H. Desch pointed out that different abstracts of the same paper, stressing different aspects, are needed by different readers.

Towards the end of the session, Professor Bernal gave his opinion that scientists should not be obliged to read more than two or three abstract journals to cover their own special work and related subjects. Abstracting organisations could well become centres for services distributing reprints.

When the working parties reported their conclusions and recommendations at the second plenary session, it was evident that there was agreement on many basic principles of abstracting. For instance, it was recognised that as the needs of different categories of readers differ, so the abstracts of a single original paper should differ. This being so, it is undesirable to suggest that only one abstract be made of any paper; the particular needs of readers are paramount in abstracting. Some institutions prefer abstracts which are no more than statements of fact, but others are convinced that critical comments, by expert abstracters competent to make such comments, may greatly add to the value of an abstract. The formation of a standing consultative committee of representatives of abstracting organisations was suggested, this committee to have only advisory functions. In this way mutual cooperation might be advanced, with general benefit. *Abstracting is an important branch of the* scientific information services, and the editors of abstracting journals should choose their material, and their abstracters, with care, and should ensure that the accounts given of published papers are factually accurate.

INDEXES AND REVIEWS

Section 3 concerned itself with indexing and other library services, and made a large number of recommendations on such matters as systems of classification, methods of reproducing copies of papers, the training and status of librarians, and other subjects.

In section 4 Sir Edward Salisbury, SEC.R.S., said that the writers of reviews should take into account the readers for whom they are composed, and should decide whether the reviews are to be objective statements of work done, or critical and selective accounts of significant work. The same point was taken up by Prof. Munro Fox, F.R.S., editor of *Biological Reviews*, who thought that critical reviews may be synthetic in that they may crystallise out new and fruitful ideas. The difficulty is to get them written by competent scientists, who are usually working to full capacity already. There is also a place for more comprehensive summaries of recent work, which, while still retaining a critical outlook, serve to guide especially those who are starting new research. This also was the view of Mr. A. King, who thought that in these days of increasing specialisation and team-work reviews are more necessary than ever before. Reviews may be written for the general public, for interested laymen, for general scientists, or for specialists.

The importance of reviews to scientists isolated from libraries and centres of research was stressed by Mr. Hugh Saunderson, of Canada. Publication of papers contributed to "symposia," or of lectures in which the speakers sum up recent work, helps to solve this problem, but needs development.

Mr. L. J. F. Brimble (*Nature*) said that the choice of reviewers was most important, and that it is wise not to retain one reviewer too long on one subject; variety and change are essential, and foreign reviewers should be asked to write for British publications. The international point of view is essential.

Finally, Prof. Murray Luck, of the United States, wondered, gently, whether the spate of original papers would be replaced by a spate of reviews; but he was not unduly depressed about it, and agreed that reviews are needed.

CONCLUSION

The conference as a whole made no proposals for revolutionary change in existing practice, but many important suggestions were made for development, progress the author, feeling it imperative to add more recently acquired knowledge, was forced to dispatch his corrigenda up the same route. He rightly feared that the eventual date of publication would find many corrigenda breathlessly but vainly on the ascent, and his colleagues would remain unaware of these improvements. I cannot but think, however, how pleased I shall be to have a statutory public of senior officials for my articles. It is surely better to be read with distaste then to be completely ignored.

This recalls to my mind an incident in my humble service in His Majesty's Forces. My length of service and lack of any outstanding characteristics in my opinion warranted promotion. It merely remained to bring my name before those in authority. A recent circular had particularly stressed the chances of original thought and research available to all M.O.'s in the Service. Those who complained of lack of work were self-confessedly incapable of profiting by the material at hand. I forthwith took this to heart. My work was the inspection of a large number of men for pediculi pubis, an arthropod which as a backward student I had never seen, and, since the men I inspected had been thoroughly examined a few days previously, I did not expect to see now. However, watching the inguinal regions flicker like a moving picture past my field of vision, I sat casually visualising their owner's facial appearance. After the first few thousand I became remarkably proficient. The words of the circular came to my mind and I set down a few notes on my technique. Tables of frequency distribution and standard errors were to follow. Maybe, I thought, identity-card photographs and fingerprints would become things of the past. Spies could be recognised instantly. A short preliminary note was prepared for publication and submitted.

Alas, all that came of my patient work was a telegram dispatched with quite incredible promptitude, stating that the article was not, repeat not, to be published. My dreams of the new science of inguinal-phrenology were dashed to the ground and I ended my service with he same rank.

* * *

The poison pen of an anonymous-letter writer became busy in our hospital. At last his efforts could no longer be ignored; he alleged "something shocking in the woodshed." Suspicions all *pointed to one* man, whom I proceeded to interview. I had imagined myself something of a sleuth and by *no means unsuccessful* as a cross-examiner; but, try as I might, I could not penetrate his protestations of innocence. *Later the police* referred the specimens of handwriting to distant experts who quickly and confidently diagnosed that he, and only he, could have written the letters. I was amazed by this calligraphic certainty and by the speed by which a detective secured, in as many seconds as I had wasted minutes, a signed confession and complete retraction. Incidentally, we did not prosecute; the man resigned and showed his gratitude for leniency by writing openly to those in high places making unfavourable comment against our services.

* * *

Attending the B.M.A. Representative Meeting gave one a grand opportunity to visit Cambridge once more. To live again in college after nearly a quarter of a century is a wonderful experience. Apart from the delightful set of rooms, the marvellous cooking, and the service, there is the atmosphere, hard to describe but very real—something not apart from everyday life but an inspiration to live a full life, surrounded by beauty. To men in their formative years this contact with a society dedicated to learning as the ideal must have a profound and lasting effect, shaping their attitude to the world at large for the rest of their lives. Despite the many superficial changes the fundamentals are the same—to be afraid of nothing strange or new while keeping the best of the past; to be confident in the superiority of the mind while enjoying the things of the body; to be determined to give of your best to the material world but seeking inspiration, uninhibited by prejudice, in the spirit.

Letters to the Editor

BENEVOLENT FUND APPEAL

SIR,—Westmoreland Lodge has been opened as a residence for some of our beneficiaries; and we now need a sick bay or hostel where care and special attention can be given to residents during illness and in their declining years. This is a most urgent and pressing problem.

There recently appeared in the medical press the statement that the Medical Insurance Agency had entrusted to the Royal Medical Benevolent Fund £1000. I should like to amplify this. The cheque we actually received from the Medical Insurance Agency was for £1200. The agency gave full discretionary powers to the committee, though expressing the desire that £1000 be allocated to form the nucleus of a fund to establish proper provision for the sick and infirm. My committee, realising that the need is so very urgent, has allocated the whole of the gift of £1200, together with the income-tax which will be recoverable under this covenant payment, to form the nucleus of a special fund. With this magnificent opening I am making an appeal to the profession to enable us to complete the project. Whole-hearted approval has been shown of our determined efforts to give residential accommodation which we have been able to do through the generous bequest of the late Dr. Arthur Holdsworth Davis. We now ask the profession for the necessary financial support to establish a hostel for the sick and infirm.

Contributions should be marked "Westmoreland Lodge Sick Bay," and forwarded to 1, Balliol House, Manor Fields, Putney, London, S.W.15.

C. L. BATTESON
Honorary Treasurer,
Royal Medical Benevolent Fund.

SUPERNUMERARY NIPPLES AND NEUROSIS

SIR,—Dr. Harper's observations (June 12) may be extended in a curious way. Many years ago I was interested in the charming of warts. It is common knowledge that the application of the milky fluid from the broken stems of various plants is one of the many recommended cures. So is that of saliva.

My first attempt at charming was an encouraging success. When an intelligent boy of about 13 stretched out his hand for his case-sheet I noticed that it was covered with warts. There must have been at least 50 altogether, for I counted 10 large ones on the thumb alone. Most of us have used a thumb as a supernumerary nipple; and how else shall a cigarette or a pipe be regarded?

The boy, who had access to a chemical laboratory, had for some months tried several reagents, including strong acetic acid, without success, and now eagerly agreed to try my method. I took him on one side, and, after binding him to the utmost secrecy, told him to touch each wart with the tip of his wet tongue every morning the moment he awoke, before any food whatever had passed his lips, for then the saliva was peculiarly poisonous to warts; and in a month they would have gone. They went. By a subterfuge the boy had been weaned.

I related this success to the sister in charge of the school clinic, who asked if I thought that she could cure in the same way a boy of 8 whose many warts persisted in spite of all her treatment. I thought she might if she attended to the ritual properly. A month later she reported total failure, whereupon I sent for the boy and asked how he had carried out the instructions. He said that each morning he had got some spit on the tip of his finger and touched the warts with it. As for secrecy, he had only told his school-teacher, who had laughed mockingly. I looked grave, chided him for his slackness, and said that if he really wished to get rid of the warts he must steal a potato from his mother's store, halve it, touch each wart with the raw surface, and then bury the potato in the backyard by the light of the full moon—all in the greatest secrecy. At the end of a month the warts had disappeared. Another subtle weaning.

A sceptical colleague, a man in his fifties, amused by my fantastic stories, asked if the process would work stage the sufferer may begin to appreciate that although the larger satisfactions may have to be deferred for some time at least, life has still a good deal to offer on a somewhat lower plane. When interest is kept alive, even by matters of apparently trivial import, frustration and depression are largely kept at bay.

During this phase, therefore, the patient needs to be encouraged both to take an interest in his immediate environment and to become, as it were, a natural part of it. Hospital competitions, entertainments, and talks on the internal broadcasting system all combine to create a community feeling, and if the patient himself can take even a minor *active* rôle in such things his interest will be magnified and he will get to know and be more at ease with his surroundings. Some form of occupational therapy should also be undertaken—preferably of such a nature as to prove a lasting source of interest.

As recovery proceeds attention shifts once more from the comfortable and comforting minutiæ of the little sanatorium world to the realities of life outside. But there is no longer an impulse to rush back full tilt into the turmoil—the outside world now assumes a somewhat frightening aspect. Depending, of course, on the patient's temperament, the length of his illness, and the satisfactoriness of the result obtained, there is nearly always a lack of confidence, combined with an unwillingness to leave the safety of the harbour for the perils and buffetings of the high seas.

The patient now needs to be prompted to increase his range of activity and interests, and it is well to turn his gaze more and more in the direction of the outside world. Step by step this return towards normal life, modified by suitable precautions, should be encouraged, the patient gradually gaining confidence and losing his sense of incapacity and dependence.

After leaving the sanatorium confidence may return rather too quickly, and the danger then lies in succumbing to the temptation to resume full normal activity. In the sanatorium rest-hours and regular habits are accepted without question; outside they may lead to a raising of eyebrows, awkward questions, and general inconvenience. Usually the patient feels too well to experience any physical need to continue his routine and does not realise how thin may be the ice beneath him. There is even a perverse determination to prove to himself and others that he can do as much or more than the next man, in spite of his having had tuberculosis. Advice to go slow is quietly ignored, or may even be resented, according to its source.

A sharp lesson is often required at this stage to underline the fact that the ex-patient has limitations, and that it is better to carry part of the burden all the way than all of it for a short time only. This is not easy to realise; it may well be only after a relapse has occurred that its essential wisdom becomes clear.

* * *

From the foregoing it will be apparent that in pulmonary tuberculosis the emotional factor plays a highly significant part at all stages of the disease. The difficulty lies in securing an acceptance of limitation without developing an invalid outlook. The limitation may be relatively little or very considerable, and the optimum level of activity has to be determined in each case—largely by the patient himself regarding day-to-day matters.

One rather good way of looking at the problem is to regard oneself as entirely normal except for requiring considerably more rest than other people, and this is best secured by keeping to a regular routine. Anything causing undue tiredness should be noted and not allowed to happen again. Rest hours may not be sacred but they are certainly very important to the physical economy of the tuberculous patient, and the more he does the more important they become.

In England Now

A Running Commentary by Peripatetic Correspondents

AT Wimbledon today I studied nervous reaction to excitement on the Centre Court. A svelte case in front of me threw her head into her hands with each match-point, and at 40–30 would pull the lobe of her father's left ear, until it became quite ragged at the end of play. A man on the other side of me lost his chin in his collar with every rally. Somebody else stood up in frenzied passion just when the climax of a match was reached and yelled a protracted gibberish which sounded like the alphabet backwards. In the mixed-doubles I found mental solace in taking an occasional mouthful of the white tulle veil which formed the hat of a beautiful girl in front of me. By the end of the day her head was bare and I had acute indigestion.

* * *

Old Joe Honeysuckle, who "does" our garden, is a great believer in herbal remedies. "There'd be no need for this loan from Ameriky if people only knowed the treasures that lay under their feet," he said. "That there dock you're treadin' on, for instance. Tim Gurglethwaite had two boils on the back of his neck and tried all sorts of medicines and went time and again to the doctor, but they wouldn't go. I told him to dig up a dock root, boil it, and drink the water. They went, and they didn't come back. When I was a young man I once had a boil, and dock root got rid of it, and I've never had another since." "But," said I, thinking on post-hoc-propter-hoc lines, "I once had a couple of boils thirty years ago, and whatever I put on them then, and whatever I didn't put on them, must have cured them, because I've had none since." "Ah," replied Joe wisely, "but, you see, in my case I didn't put nothin' on them. I drank the water."

"Then there's broom tea," he added after a pause. "George Puddyphut came along one day to see me with three new cuts in his boots. 'What's wrong with your feet?' I asked him. 'I bin in hospital three weeks,' he said, 'and under the doctor afterwards. They tell me I've got lumbago and rheumatiz, and they can't do nothin' for me.' 'That's no lumbago nor rheumatiz,' I told him, 'that's dropsy.' And I showed him how to make broom tea to cure it. He come back a week later wearin' proper boots, and a week after that he went to work in leather gaiters."

Joe was a shepherd in his younger days, and it must have been from watching the vet. that he acquired his interest in experiments. Two sheep died, one of galloping consumption, the other of pneumonia. Joe put a piece of lung from each in separate jam-jars, dated and labelled them, and put them in the sunshine. After a while the tuberculous lung, according to Joe, was full of "little white germs," falling down like a snowstorm, and the lung became smaller and smaller till there wasn't none left, only water in the bottom of the jar. The other lung, the pneumonia one, stayed hard and didn't fall away to nothin'. "That shows," opined Joe, "that the two sheep died of different diseases, doesn't it?"

On another occasion Joe took a potato infested with wireworm and put it in a glass jar with a metal lid Long before the wireworms pupated, many small cocoons appeared on the walls of the jar, and from these hatched minute flies. "That," said Joe, "proves there was flies' eggs in the potato, don't it?" I pointed out that the cocoons were on the sides of the jar and not close to the potato; that he had pierced the metal lid with a hole large enough for the fly to enter and lay eggs; and that he had probably not sterilised the jar in the first instance. Joe looked reproachfully at me for criticising his scientific experiment, and stoutly maintained that it proved the folly of using artificial manures.

* * *

Some writers have expressed fears that the National Health Service Act may lead to censorship of medical articles. One learned and apparently prolific author has described the fate of his works when on military service. His communication passed from one senior officer to another in an ascending and vicious spiral; during this hospital at all. However, in spite of this early treatment in bed, the paralysis-rate of 0·36 per 1000 troops at Catterick Camp compares unfavourably with 0·12 in Eccles[6] and 0·06 in Glasgow[7] per 1000 persons over 15 years of age in 1947.

Southern General Hospital, Glasgow. G. JOLY DIXON.

ATTACK ON RHEUMATISM

SIR,—The many letters you have published under this heading have demonstrated the wide interest in the subject; but few have had any bearing on the aspect that was in my mind in the letter that I wrote at the outset. This stressed the importance of the general practitioner in the attack, and pointed out how he might be better trained for the important part he will always have to play. Probably the most important stage of all in the campaign is the recognition of the earliest signs and warnings, and of the influence of hygienic conditions, food, housing, occupation, psychological factors, &c., which come under the observation of the family doctor. The specialist in whatever branch seldom sees these in action; he sees only their effects. One may perhaps compare the rôle of the general practitioner to that of the politician who sees and is concerned with those causes which lead to war, while the specialist only comes into action when the conflict has begun or may even be far advanced. Too often the attempt to control and to remedy the resulting damage is only begun when it is too late. The orthopædist, for example, who might be called in at the earliest stages, is by many only supposed to be of service to devise splints and supports, or even to operate at the last stage in the disastrous history.

Let the family doctor and the medical student be taught the ætiological factors and the prodromal signs, so that if his efforts fail to prevent or cure he may recognise the moment to call in the colleague who has wider knowledge and experience, under whatever designation he may elect to practise, provided it is not a narrow specialty. The specialist with a limited outlook may be a danger rather than a help, and the last state of the patient be sans teeth, sans tonsils, sans money, sans everything which makes life worth living. The general practitioner should be assisted, not superseded, whenever possible.

Too often one hears a patient say: " Oh, my doctor takes no interest in rheumatism "—a deplorable reflection on the education which has failed to teach him that no disease or group of diseases touches medicine at so many points or needs a wider knowledge of medicine in general. On the other hand, many practitioners could make valuable contributions to our knowledge of the rheumatic diseases, both as to cause and treatment, from their wide observation and experience. I should like to hear more from them before this correspondence ceases. We are wandering too far from the highway into fascinating byways which may prove of little practical value.

Ashbourne. CHARLES W. BUCKLEY.

SCHOOL DOCTORS AND THE ACT

SIR,—Your correspondent " Father of Eight " asks " What is the position of school doctors under the Act? " He then proceeds to give not only the wrong answers to his own question but to make definitely misleading statements.

The Medical Officers of Schools Association, of which I was president from 1946 to 1948, asked the Governing Bodies Association to negotiate with the Ministry of Health on our behalf, and the result was a letter from the secretary of the Ministry of Health stating that for additional services not covered by the provision of general medical services, such as the carrying out of routine or special examinations and the giving of advice on general health matters to the school authorities, the school authorities would presumably wish to make some special payment to the doctor. This applied particularly to the part-time doctor, and a separate sentence was added for those public schools which employed whole-time doctors to the effect that if this doctor was receiving a whole-time salary from the school authorities, arrangements could be made with him to authorise payment of the appropriate remuneration due from the executive council direct to the school authorities. " In any event, these authorities will wish to remunerate such doctors for services provided outside the scope of the National Health Service, such as those referred to earlier." This has been confirmed by administrative memorandum no. 284 of June 18, 1948, from the Ministry of Education. This refers to the Minister of Health's circular to local education authorities, governing bodies of special schools and secondary schools with boarders, training colleges, &c., and says:

> " Where the doctor provides general medical care under the National Health Service in accordance with the arrangements set out in this memorandum, he will be paid by the Executive Council. He will not be entitled to charge any additional fees for these services, but it will be open to the authorities of the school or other residential educational establishment to pay him for, e.g., routine medical examinations made in particular cases at their request. If the doctor is receiving a whole-time salary from the school or establishment, he will be able to authorise the Executive Council to pay direct to his employers the fees due to him from the Council."

These quotations from official letters show that the verbal message that " Father of Eight " obtained from the Ministry of Health is, in the words of a popular comedian, " Not worth the paper it is written on."

The amount of extra work that the school medical officer has to do over and above just seeing after the sick is enormous if he really takes his duties seriously, and the Governing Bodies of Schools Association rightly appreciate that the labourer is worthy of his hire. I think " Father of Eight " will appreciate the justice of the Ministry of Health's and the Ministry of Education's official recommendations.

Rugby. R. E. SMITH.

LEUKÆMIA PRESENTING WITH NEUROLOGICAL MANIFESTATIONS

SIR,—Having read Dr. Gauld's article (June 19), and since only 5 out of 69 cases of leukæmia presented initially as a meningitis in the series of Schwaub and Weiss,[1] I feel it may be worth recording the following case, which also presented as meningitis.

A boy aged 4 years and 4 months, an only child of a healthy family and with no history of previous significant illness, was admitted to the Hospital for Sick Children, Great Ormond Street, under Dr. Sheldon, with the history that six days before admission he complained of a " nasty taste " which caused him to vomit once. Later the same day he knocked his head with no undue violence, but complained of the pain far longer than was thought usual for him; subsequently and up to admission he did not complain of any headache. Five days previously he had vomited twice in an effortless manner, and, becoming increasingly drowsy and listless, had vomited repeatedly. A dry cough had been noted for 3–4 days only.

Examination.—Normal size for age. Temp. 100°F; pulse-rate 110 per min.; respirations 36 per min., face flushed. Practically comatose, but consciousness varied and he responded to questions slowly. Enlarged tender glands in the posterior triangle of the neck, and smaller enlarged glands in the axillary, epitrochlear, and inguinal regions. Right side of chest bulging forwards slightly, and respirations irregular. Liver felt one finger-breadth below the costal margin; spleen just palpable. Flexion of the neck produced severe pain and rigidity; Kernig sign positive. Pupils constricted, but reacted to light. Some early papillœdema with engorged vessels; no choroid tubercles seen. No petechiæ or other abnormal physical signs.

Progress.—At first the child was thought to be suffering from *miliary tuberculosis* with accompanying meningitis, but the cerebrospinal fluid was normal in every respect. Next morning he complained of occipital, arm, and leg pain. The liver had enlarged to 2 finger-breadths and the spleen to one finger-breadth below the costal margin.

Until now a definite diagnosis had not been made, but a blood-count revealed acute lymphatic leukæmia, the blood-picture being as follows: red cells 3,300,000 per c.mm.; Hb 55% (7·7 g. per 100 ml.), white cells 820,000 per c.mm. (composed entirely of lymphocytes and lymphoblasts).

---

with him. He had had a wart on his shin for forty years which had defied treatment. Not being an acrobat, he said, he could not touch it with his tongue. Besides, he knew the thing was just spoof, and he had no faith. I assured him that in the circumstances it would work if he applied the saliva with his finger. Either his knowledge was insufficient or his faith greater than he knew, for the wart faded away.

I should have hesitated to put these experiences on record but for the fact that Dr. Millais Culpin has told me that in his early days at the London Hospital patients with warts were generally referred to a certain sister who charmed them away. Moreover, I have heard a leading *skin specialist declare his belief in the efficacy of* charms. If tissue change can indeed be thus induced, it is reasonable to suppose that corresponding emotional impulses may actually cause the warts. In my boyhood I was warned never to wash my hands in water in which eggs had been boiled, lest warts should result; and Wynne Parry has recorded[1] how a young woman's recurrent attacks of iridocyclitis were traced to mere contact of the unbroken skin with eggs. It is the old story of sexual prohibition in another disguise.

In his communication on bodily changes during abreaction Moody[2] carries the matter further; significant organic lesions have developed before his eyes as a result of deliberately provoked emotional stress, and the manifestations have borne a definite relation to the nature of the emotion. His observations support the less easily proved dramatic phenomena I described in an article on sympathetic disturbance in connexion with thoughts of death by hanging.[3]

Some day someone may link up the capricious wart with the variable facial pimple that announces the approach of a menstrual period, the acne that tells of a difficult adolescence, the stye that is supposed to yield to the magic touch of a wedding ring, and—who knows? —the malignancy that seems to hover about a chronically irritated nipple or mole. Irritation can come from within as well as from without.

Portsmouth. W. S. INMAN.

AFTERMATH OF A CAUDA-EQUINA LESION

SIR,—In the article on this subject in your Disabilities series (April 17, p. 608) the patient makes a plea for a very light calliper. For some time past I have been experimenting with a thin wall high-tensile steel tubing, which I have found most satisfactory. The tubing has an outside diameter of $^{3}/_{8}$ in. and a wall $^{21}/_{1000}$ in. thick. The steel is the kind used for golf-clubs, and it reduces the weight of the calliper by as much as two-thirds. The tubing is supplied by Messrs. Accles & Pollock, of Birmingham.

Physical Medicine Department,
General Hospital, Northampton.
T. K. DAVIDSON.

THE GEOGRAPHICAL ORIGIN OF NURSES

SIR,—Dr. Barnet Woolf's statistical demonstration (June 19) of where more recruits to nursing could be found is most interesting.

It may be worth while reminding ourselves once more that compulsory residence for nurses is a relic of the Nightingale rehabilitation of nursing in 1860 and afterwards. At that time young women of the type Florence Nightingale wanted could not have lived in the neighbourhood of most hospitals, and there was then no transport to bring them in from more respectable neighbourhoods. Florence Nightingale relied on the influence of the nurses' home to safeguard the respectability of the nurses.

In modern times one of the disadvantages of nursing as compared with other work is payment largely in kind. If the nurse were *paid a gross salary* so that she had more command over her earnings, it would be much easier to compare her position fairly with that of other students and employees. Girls living at home could contribute to the family income when necessary. Those for whom accommodation had to be found would enjoy a greater sense of freedom if they paid for it themselves.

London, W.2. G. B. CARTER.

FOR AND AGAINST MYANESIN

SIR,—A short while ago I wrote[1] saying I had never seen a thrombosis following 'Myanesin,' and I wondered whether this untoward effect could be due to errors of technique. It was kindly pointed out to me at the time by leading anæsthetists that I had been very lucky and that in time I must encounter this trouble.

I have now seen it—a thrombosis 12 in. long in the right arm, rendering the patient (who is perfectly recovered from her hysterectomy) unable to write, darn her husband's socks, or tolerate the contact of the arm with her body. Since seeing is believing I now apologise *to the anæsthetists for the suggestion that errors in* technique could be the cause of the thromboses.

London, W.1. KEITH VARTAN.

GROWTH-RETARDING FACTOR

SIR,—In their preliminary communication of May 15 on a growth-retarding factor in maize bran, Mr. Borrow and his colleagues gave an analysis of mice weights and of diets, but they made no mention of taking a peep inside their dwarf mice. Perhaps they have forgotten the history of thiourea? In 1941 New Zealand investigators reported retardation of growth in rats fed partly on rape or turnip seeds. Without a consideration of imbalance of amino-acids or multitudinous growth factors they labelled the seeds as possessing a goitrogen because their dwarfs had enlarged, cellular thyroid glands. Later they isolated the goitrogen thiourea from rape and turnip seeds. It seems essential, in the present work, to eliminate such a possibility before entering the unknown.

DECUBITUS IN THE MENINGEAL STAGE OF POLIOMYELITIS

SIR,—Dr. Ryle's interesting article of June 19 (p. 945) demonstrates the wide tendency to accept Russell's view[2] that early immobilisation of cases of poliomyelitis decreases the severity of paralysis. Perhaps it would not be out of place to comment on the premises for this conclusion.

Russell, who questioned 44 convalescents, found he could distinguish a meningeal preparalytic phase in 41. Of the 20 cases who had had abortive or mild attacks 10 had been treated in bed from the first appearance of meningeal symptoms, and of the 21 who developed paralysis only 1 had taken to bed during this stage. Russell's conclusion that these figures are significant would, however, be invalidated if an error occurred in sampling. It is here suggested that since Russell's observations were confined to convalescents, and since his cases were collected from four different cities, he only saw that small proportion of abortive cases which happened to be recognised in the meningeal stage. This method of sampling was likely to reveal a much higher proportion of paralytic cases. If so, the history obtained from the latter gave a more average picture of the behaviour of patients in the meningeal phase.

Paul and his co-workers,[3] Casey and his colleagues,[4] and Ryle have discovered abortive cases only by careful observation of contacts; and these and other writers agree that the abortive cases greatly outnumber the paralytics. Casey even suggests that the ratio is 98 abortive cases to 2 paralytics.

During last year's epidemic 7 paralytic cases, 1 fatal case, and 10 abortive cases, were treated at Catterick Camp and later described by me.[5] Of the paralytic cases, 6 were treated in bed from the start of the meningeal stage, but after thirty-six hours to four days developed paralysis. Similar early treatment was *instituted in the abortive cases.* These men regarded their meningeal symptoms lightly, and I concluded that in civilian life most of the paralytics would have been admitted to hospital only after onset of paralysis, and that most of the abortive cases would not have come into

Parliament

Children Bill

In moving the third reading of the Children Bill in the House of Commons on June 28 Mr. **Chuter Ede**, the Home Secretary, said it was some tribute to the work that could still be done by enlightened people using the more respectable parts of the press for the ventilation of public grievances that this great measure had virtually grown from a letter written to the *Times* by Lady Allen of Hurtwood. The Bill placed new and heavy duties on local authorities and brought into being the important post of children's officer. Mr. **Kenneth Lindsay** regarded the measure as transitional pending a more enlightened conception. Commander **Galbraith** urged that in the appointment of children's officers too much stress should not be laid on academic qualifications. Mr. **Younger**, replying to the debate, paid a tribute to the voluntary organisations which, he said, were responsible for a large number of children and to which a great deal of initiative would still be left.

Medical Service in Factories

In the adjourned debate on the second reading of the Factories Bill on July 2 Dr. H. B. **Morgan** expressed deep concern in regard to this measure. He regarded it as retrograde. The complement to the National Health Service Act would have been an Industrial Medical Services Act for which there was a great desire among the organised workers of the country. The part of the Bill to which the trade-union movement took most exception was the new provisions in regard to the examining surgeons whose duties were defined in the main Act of 1937. Not only was there to be a change of name, but a doctor selected by employers, individually or in combination, or the industrial medical officer appointed by the employer in a particular factory, would have the option of being appointed as a factory doctor and be able to fulfil all the duties formerly imposed on the examining surgeon, who was supposed to be an impartial person appointed by the appropriate Government department. Dr. Morgan suggested that the Minister should make this provision particular instead of general, and take authority to say that the company's doctor should not usually be appointed to the post. The decision on recruitment into industry, instead of being decisive, should be subject to appeal. The Bill, as a whole, was not the way in which the Government should handle an industrial medical service. Only the large factories had industrial medical officers under the regulations made by the former Minister of Health. What was being done about the small factories in which there might be as many health hazards as in the large ones?

After further debate Mr. G. **Isaacs**, Minister of Labour, said he had a great deal of sympathy with Dr. Morgan's point. He knew that if the firm's doctor was the one who was to certify whether a man had contracted a particular disease in that firm or not, the worker might have a doubt in his mind, although he (Mr. Isaacs) did not believe that a doctor would be swayed from his professional ideals. He had given an undertaking to examine with the most meticulous care any amendments designed to remove doubts and misunderstandings on this score. If he thought the Bill would retard the introduction of a full industrial medical service he would hesitate about giving it his support.

The Bill was read a second time.

Supply of Artificial Limbs

In the House of Commons on July 1 Mr. **George Buchanan**, Minister of Pensions, said that arrangements had been made which would enable every firm which was able to produce an artificial limb of high quality to continue in production. These arrangements were:

(1) Every patient requiring a limb will be asked to attend at one of the Ministry's limb-fitting centres reasonably close to his home. He will there be examined by a Ministry of Pensions experienced and highly qualified limb-fitting surgeon who, in consultation with the surgeon who performed the amputation, will prescribe the type of limb required for his particular stump.

(2) The patient will then be given all necessary information to enable him to make his choice of limb from lists of makers whose limbs have been approved by the Ministry of Pensions and who have entered into a contract for this purpose.

(3) If he chooses a limb such as is now being supplied to war-disabled pensioners he will get this as a free issue. If he chooses an approved limb of some other make and this costs more, he will be charged the excess.

(4) If he chooses the free limb, he will be dealt with throughout at the Ministry's limb-fitting centre. If, however, he chooses another approved limb he will be put into touch with the maker who will arrange for measurements to be taken and fittings to be given. He will be required to attend at the Ministry's limb-fitting centre when he has been satisfactorily fitted in this manner where he will be examined by the limb-fitting surgeon, who will ensure that the limb is satisfactory in all respects.

The object was to allow the patient a reasonable choice in regard to the type of limb and maker, while putting at his disposal all the specialised medical skill acquired by the Ministry's limb-fitting service.

In answer to Dr. **Haden Guest**, the Minister said that his department spent a considerable amount of money and time on research. "It is our purpose not only to make the results of this research available to the main Government contractors, but also to every maker of artificial limbs." He told Sir **Henry Morris-Jones** that he regarded the scheme as a fair compromise and trusted that it would be given a chance to work. After a reasonable time it could be reviewed.

QUESTION TIME

N.H.S. List of Doctors

Mr. A. C. **Bossom** asked the Minister of Health whether he would state when the list of doctors in the Health Service, promised for June 21 or soon after, would be available in post-offices and libraries, so that the public might choose their doctors.—Mr. **Bevan** replied: I asked executive councils to get these lists into the post-offices on or as soon as possible after June 21. Some of them have already done so: others, including London, have not yet succeeded, but will do so as soon as possible. Any member of the public in an area where the lists have not yet appeared can apply to the executive council for the names of doctors on the list in his neighbourhood.

Answering a further question he added: I always expected that, in consequence of the tardiness of many of the doctors to sign up on these lists, there would be inconvenience after July 5. The House will recollect that the official propaganda of the profession itself told the doctors that there was no hurry to sign up, and the result is that we have had a large rush of doctors in the last few days, making it quite impossible for executive councils to put up complete lists in time. Furthermore, many of the local medical committees of the profession have asked the executive councils not to put up incomplete lists, because they said it would be unfair to those doctors who had not yet signed up, so that, in some instances, and in fact in many cases, it is entirely in consequence of the conduct of the official propaganda by the medical profession, for which I refuse to accept the slightest responsibility. The House will recollect that I myself issued leaflets urging the profession and the public to sign up.

Mr. **Ralph Assheton**: I am sorry that the Minister has seen fit to put the blame entirely on the doctors, which we on the Opposition side of the House certainly cannot accept. Can the Minister indicate where communications may be addressed to these executive councils?

Mr. **Bevan**: The names and addresses of the executive councils are put up in the post-offices and in some cases in the public libraries. Part of the difficulty in London is that some 1500 general practitioners have to be classified for their particular areas. Obviously, putting up 1500 names in one list is of no use to anybody at all.

Major **Tufton Beamish**: Is it not absolutely unfair to put the whole blame for the delay on the doctors, than whom there is no more public-spirited body in the country? Is

Radiographic examination of chest showed large mediastinal glands, but there was no evidence of metastases in the long bones or skull. On the 4th day after admission he was still conscious, but had severe head retraction; the cervical glands had enlarged further, and the spleen was now down to the umbilicus and the liver 3 finger-breadths below the costal margin. His condition deteriorated rapidly and he died 11 days after admission—i.e., 15 days after the onset of the first symptoms. Permission for a necropsy was not obtained.

The pronounced signs of meningitis could hardly be explained by inflammation of the comparatively small cervical glands causing local irritation and spasm, and it must be presumed that there was infiltration of the meninges.

I wish to thank Dr. Wilfrid Sheldon for permission to publish this case.

London, N.W.3. BERNARD M. LAURANCE.

INCOMES FOR SPECIALISTS AND GOVERNMENT MEDICAL OFFICERS

SIR,—The Institution of Professional Civil Servants, as the Civil Service body representing medical officers in the Civil Service (other than those employed in the Ministry of Health and the Board of Education), was very interested in the letter in your issue of June 19, signed by "A Stepchild of the Profession." It is time that attention was drawn to the inadequate salaries paid to medical officers in the Civil Service. The service requires doctors with high qualifications and wide experience, but owing to the low salaries and poor prospects which are offered it is finding great difficulty in recruiting candidates of suitable calibre, and in retaining those it has been able to recruit. Indeed, those who have been in the service for many years are now seeking employment outside the service, even when this means that they will lose the valuable superannuation rights which they have earned to date. The remuneration to be enjoyed by general practitioners and consultants and specialists under the National Health Service is so much higher than that in operation in the service that, unless immediate action is taken, the service must resign itself to losing the best qualified of its doctors and to recruiting substandard candidates who will be unable properly to carry out the highly responsible duties now assigned to medical officers in the Civil Service.

This institution has already written to the Treasury pointing out that the difficulties which it has experienced in recruitment will now be still further increased, and asking it to consider a revision of the salary scales of medical officers in the light of the Spens reports.

R. MILLER
Acting General Secretary,
Institution of Professional Civil Servants.
17, Hans Place, London, S.W.1.

EPILEPSY

SIR,—I read with great interest the article on epilepsy in the "Disabilities" series. As the writer points out there is a need to educate the public and those in charge of industry about epilepsy. In this respect we are several steps behind the United States, but moves are being made which I think should be made known—even to the medical profession, who are familiar with the disability but not necessarily with its social and industrial problems.

The Ministry of Labour has circulated a leaflet on epilepsy (form DPL5) to selected employers all over the country, and the Disablement Resettlement Officers have followed this up by personal visits. The leaflets are also available at local employment exchanges. But this, of course, touches only the fringe of the employment problem and much more needs to be done. A group of people in Birmingham have asked the Ministry of Labour to set up special workshops for epileptics unfit for industry but not seriously enough handicapped to go into a colony or to remain at home doing outwork. Alternatively we want places definitely allotted in the Remploy factories. In order that epileptics can be recommended to employers with more confidence special stabilisation centres or clinics are required, to work in close contact with industry. Two such have already been set up, at St. John's Hospital, Battersea, and at All Saints' Psychiatric Clinic, Birmingham. The National Hospital, London, is making a social survey, and there is an interesting "half-way house" experiment in being at St. David's, Edmonton.

Some of us feel that to make any real progress we need two things soon: a national association and a Government working party.

Birmingham. H. HALSTEAD.

SIR,—I should like to thank the author of that remarkable account of epilepsy from the patient's point of view, which appeared in your issue of June 26. One does not get to know these things in the ordinary way.

Granted that the fit is a very individual matter, it is good to know that some patients do not find their attacks unpleasant, and may even have a feeling of extraordinary wellbeing on coming round. That the aura can be worse than the attack, and in particular that this sensation may persist after attacks as such have been controlled, shows that we must not rest until these patients have obtained complete relief. Lennox[1] mentions an almost identical case, in which the persisting aura was quelled by means of 'Mesantoin' (methylphenylethylhydantoin).

London, W.1. H. PULLAR-STRECKER.

NEURALGIC AMYOTROPHY

SIR,—The syndrome described by Dr. Parsonage and Dr. Aldren Turner (June 26) appears to consist in essence of an asymmetrical, patchy, atrophic paralysis of the muscles of the upper limb with a predilection for the shoulder-girdles, combined in some cases, with mild cutaneous sensory loss. The picture is highly suggestive of a mononeuritis multiplex. Kernohan and Woltman[2] found this type of neuritis in 20% of their cases of polyarteritis nodosa and were able to demonstrate that the changes were brought about by nerve ischæmia following an obliterative arteritis of the vasa nervorum. The authors agree that their syndrome is probably identical with neuritis following serum injections, and this lends support to the suggestion that an allergic necrotising arteritis of the type found by Kernohan and Woltman is the pathological basis of their clinical findings.

Grays, Essex. R. N. HERSON.

THE PAIN CHART

SIR,—Readers have no doubt liked Dr. Keele's unassuming but important article last week. His investigation has led him to suggest that irregularity in the time-intensity curve shows psychogeny, total or as a considerable contributory factor. I think we can understand why a certain regularity of the chart characterises organic pain, since it must be dependent on the reaction of the diseased part to the routine influences in daily life, as well as to the course of metabolic processes.

May I point out that genuine psychogenic pain occurs sometimes at regular intervals and hours? This may be the case when pain is the presenting symptom of a severe psychoneurosis, and not merely a component of an organic pathological process or the product of the patient's reaction to such an illness. The pure psychogenic pain occurring at certain hours (sometimes on particular days of the week or month) points to a trauma that took place at a certain time. If this event occurred during the night, the patient may be awakened by his pain at a certain stereotyped hour. Apart from such rare cases, the purely psychogenic pain, however troublesome otherwise, does not disturb sleep, unless accompanying an incidental dream of a specific content. Psychogenic pains of a serious nature do not respond satisfactorily to analgetic drugs—a characteristic they share with organic central pain—and even less to placebos, even though they may do so once or twice.

London, W.1. S. LOWY.

BIOGRAPHY OF SIR BERNARD SPILSBURY

SIR,—I am collecting material for a biography of my father, the late Sir Bernard Spilsbury, and would be most grateful to anyone who can supply details of his life and cases which would assist the biographer. Documents or photographs will be copied and returned immediately.

8, Eton Hall, Eton College Road,
London, N.W.3. EVELYN STEEL.

1. Lennox, W. G. *Amer. J. Psychiat.* 1946, 103, 159.
2. Kernohan, J. W., Woltman, H. W. *Arch. Neurol. Psychiat.* 1938, 39, 655.

s of aftercare which will be invaluable when the patient as home or to work. A Cardiff hospital seems to be a useful lead: on one day a month visitors of any can hope to meet and talk to the surgeon, doctor, and in charge of the case which interests them. In Cardiff, health visitors following up diabetic and peptic ulcer have attended ward rounds to bring their knowledge e management of these cases up to date.

ss B. A. Read, head almoner of St. Thomas's, showed the almoner can act as go-between for ward sister and c health nurse. Where she is in close daily touch with sisters she can often save the health visitor a personal at the hospital to discuss a minor point. Miss Read it smooths the transition of a patient from the wards he outpatient department when the almoner passes on he outpatient sister information derived from the ward r; but this seems a roundabout system. Why can't two sisters discuss the case over lunch, like the rest of. In practice, no doubt, they often do.

---

versity of Oxford

r. G. P. Gladstone has been appointed reader in bacterio-

lversity of London

wo chairs have been established in the department of hology at King's College Hospital medical school; a ir of morbid anatomy to which Dr. H. A. Magnus has been ointed, and a chair of chemical pathology to which Dr. H. Gray has been appointed.

r. Magnus qualified from Bart's in 1932, taking his M.B. Lond. he following year, and in 1937 he was awarded the gold medal pathology for his M.D. thesis. After holding a house-appointnt at Bart's he became senior lecturer in morbid anatomy there ore taking up his present appointment as morbid anatomist at g's College Hospital. During the war he served in the R.A.M.C. h the rank of lieut.-colonel. His published work includes papers the pathology of gastritis and the experimental production of illomata in the lungs.

r. Gray graduated B.SC. Lond. with honours in chemistry in 2 before taking up medicine. He qualified from University lege Hospital in 1936, taking his M.B. the following year. In 8 he obtained his M.SC. in biochemistry. He held the Graham olarship in pathology and the Bayliss-Starling scholarship in siology and biochemistry at University College, where he also ed as demonstrator in biochemistry. Later he became lecturer biochemistry at King's College Hospital medical school and biomist to the hospital. He is also honorary lecturer in biochemistry University College. He is a fellow of the Royal Institute of emistry. He has published papers on ketonæmia and on serum atment in nephrosis.

University of Leeds

At recent examinations for the D.P.H. the following were successful: G. Higgins, G. W. Knight, J. Lyons.

University of St. Andrews

At recent examinations the following were successful:

M.D.—A. D. H. MacPherson (with honours); W. L. M. Perry (with commendation); W. M. Shearer.

M.B., Ch.B.—W. K. Stewart (with distinction); I. T. Carrie, J. A. Clark, Marjorie Crumpton, J. C. Davidson, G. F. E. Edmondson-Jones, Hamish Fraser, W. A. Hogg, G. S. Nelson, J. H. Renwick, W. F. Walker (with commendation); C. K. Anderson, J. A. Black, R. J. P. Blyth, D. M. Brough, K. A. Buchanan, A. L. Cairns, T. G. Cameron, Jessie D. Carrick, Alison Chapman, D. H. Cook, I. W. Davidson, D. R. Edwards, Jack Eyton-Jones, Sheila R. Fisher, Elizabeth M. Ford, Alexander Gerrard, Mildred F. Gordon, J. G. Grounds, Margaret B. W. Gyle, Phyllis H. Jewitt, R. P. W. Kup, Tamsin M. R. Lee, Norman Levinson, Margaret S. Lewis, D. E. Macdonald, R. S. McKelvey, C. A. Moodie, D. S. Munro, D. C. Murdoch, Edith M. Nairn, Megan C. Pratt, Joan A. Robertson, Catherine E. E. Sharp, Mary E. Shelswell, A. L. Stead, P. A. N. Wainwright, F. W. Wigzell, Katharine F. Wilson.

University of Dublin

On June 30 at the school of physic, Trinity College, the following degrees were conferred:

M.D.—D. H. A. Irwin, Bernard Kernoff, Ethna M. MacCarthy, Reuben Resnekov.

M.B., B.Ch., B.A.O.—Elizabeth E. Bird, Doris J. Black, G. W. Brown, N. P. Browne, Maureen A. Byrne, J. A. Campbell, J. E. F. Coolican, C. J. Davis, R. B. Dockrell, R. F. Doyle, C. M. Elliott, J. L. England, R. B. Flood, Sheila S. Hanbidge, J. A. R. Hanna, Hetty Hool, N. B. Hool, D. T. Irwin, Anna E. Johnston, P. A. Johnston, A. L. Jones, H. A. Karrach, Margaret K. B. Knox, I. J. Kritzinger, Edith E. Kyle, D. F. V. Lane, Muriel T. McKenna, T. B. Madden, M. J. P. O'Brien, M. S. O'Grady, Dorothy C. Oswald, N. McN. Parkes, P. K. Storah, Blanche Weekes, A. M. Wiley.

L.M.—H. G. Alton.

At a recent examination the following were successful:

D.G.O.—G. P. Balouny, A. S. Choudhuri, Malak Ghannam, Salem Haydari, A. J. B. Paes.

Queen's University, Belfast

Dr. F. M. B. Allen has been appointed to the newly established Nuffield chair of child health.

Dr. Allen, who is 50 years of age, is now lecturer in infant hygiene and diseases of children in the university, physician to the Belfast Hospital for Sick Children, and physician in charge of infants at the Royal Maternity Hospital. He graduated M.B. with honours at the Queen's University in 1920 and proceeded to the M.D. three years later. After graduation he held house-appointments at the Royal Victoria Hospital, Belfast, and from 1923 to 1924 he was Musgrave research student and later lecturer in materia medica at the university. He has also served as a hospital officer to the minister of home affairs for Northern Ireland, and as a medical member of a pensions appeal tribunal. His *Aids to Diseases of Children* and his *Diseases in Infancy and Childhood* have both gone into several editions. He was elected F.R.C.P. in 1939.

Royal College of Surgeons of England

Election to the Council.—On July 1 Sir Harry Platt was re-elected and Mr. R. C. Brock and Sir Archibald McIndoe were elected members of the council. The result of the poll was as follows:

	Votes
Sir HARRY PLATT (Royal Infirmary, Manchester) ..	672
Sir ARCHIBALD MCINDOE (St. Bartholomew's)	454
R. C. BROCK (Guy's)	418
A. DICKSON WRIGHT (St. Mary's)	416
R. H. MAINGOT (Royal Free)	353
E. W. RICHES (Middlesex)	331
A. HEDLEY WHYTE (Royal Victoria, Newcastle-on-Tyne)	266
A. C. PERRY (London)	239
H. W. RODGERS (Royal Victoria, Belfast)	217
H. J. MCCURRICH (Royal Sussex County)	206
R. H. O. B. ROBINSON (St. Thomas's)	205
H. W. SYMONS (General Infirmary, Leeds)	178
M. F. NICHOLLS (St. George's)	149
A. C. PALMER (King's College)	132

In all 1588 fellows voted; in addition 22 votes were found to be invalid.

Royal Medical Benevolent Fund

Last year this fund received a record subscription income, amounting to £20,791, and, in addition, special donations totalling £1330. The proceeds of the Christmas appeal also constituted a record, and £5 was distributed as a Christmas gift to each of the fund's regular beneficiaries. With 343 additions to the list, the number of covenants is now over 1150; and last year 143 newly qualified doctors became subscribers. These figures were given by the hon. treasurer at the annual general meeting on June 29, when Lord Webb-Johnson was re-elected president, Dr. C. L. Batteson hon. treasurer, and Mr. Victor Riddell hon. secretary.

Addition to Poisons List

'Tridione' (3 : 5 : 5-trimethyl-oxazolidine-2 : 4-dione) has been added to part I of the Poisons List and to the first and fourth schedules to the Poisons Rules.

Fellowships in Diabetes

The Diabetic Association have allotted Lund research fellowships to the following:

1947–48

Dr. J. A. L. GILBERT (full-time) in the department of therapeutics, clinical laboratory, Royal Infirmary, Edinburgh: Problems in Diabetic Pregnancies.

Dr. J. HILDES (part-time) at Hammersmith Postgraduate School: Studies in Liver Glycogen.

Dr. J. A. ROBERTSON (part-time) at King's College Hospital, London: Renal Complications of Diabetes.

1948–49

Miss G. AUDY (part-time) in the department of biochemistry, University College, London: In-vitro Studies of Insulin Action.

Mr. H. H. FOURACRE BARNS, F.R.C.S., and Dr. M. E. MORGANS (part-time) at the medical unit, University College Hospital: Animal Experiments in Diabetic Pregnancies.

Dr. H. HARRIS (full-time) at the Galton laboratory, University College: Diabetic Heredity.

Order of the Hospital of St. John of Jerusalem

Promotions and appointments recently announced include:

Knights.—Brigadier Sir Stewart Duke-Elder, K.C.V.O., F.R.C.S., Christopher Armstrong, M.B.

Commanders.—Lieut.-Colonel W. S. C. Copeman, O.B.E., F.R.C.P., Surgeon Rear-Admiral Sir Henry White, K.C.V.O., O.B.E., F.R.C.S., K.H.S., Surgeon Rear-Admiral C. E. Greeson, C.B., M.D., K.H.P.

Associate Commanders.—Khan Bahadur Abdul Hamid, M.B.E., M.B., Major-General A. N. Sharma, M.B., I.M.S., P. C. Roy, M.B.

Officers.—Cecil Hibbert, M.D., J. D. Ingram, M.D., R. G. Selby, M.B., Frank Law, F.R.C.S., E. K. Macdonald, O.B.E., M.D., Surgeon Captain William Colborne, F.R.C.S., R.N., Surgeon Captain F. G. Hunt, C.B.E., M.B., R.N., Prof. Philip Farrugia, M.D., John Lawrence Johnston, M.B., Harry Scholefield, M.B., J. A. Davies, L.M.S.S.A., J. P. J. Jenkins, O.B.E., M.R.C.S., G. W. H. Townsend, M.B., Travis Hampson, M.C., M.B., Rhys Paton, M.R.C.S., N. G. W. Davidson, O.B.E., F.R.C.S.

Associate Officers.—Lieut.-Colonel Diwan Pitamber Nath, M.B., I.M.S., Captain Khan Bahadur N. J. Vazifdar, M.B.E., L.M.S., Lieut.-Colonel G. D. Malhoutra, O.B.E., M.B., I.M.S., Dr. Chit Tin.

Tuberculosis Scholarships in Denmark

The Danish National Association against Tuberculosis invite British doctors to visit Denmark to study the measures taken there against the disease. A limited number of scholarships are also available. Further particulars may be had from the association, 21, Store Strandstraede, Copenhagen, K., who offer to help their visitors in making travelling arrangements.

The barony conferred on Sir Alfred Webb-Johnson in the Birthday honours has been gazetted by the name, style, and title of Baron Webb-Johnson, of Stoke-on-Trent in the county of Stafford.

Appointments

DOUGLAS, D. M., M.B. Lond., M.R.C.P.: asst. physician, Royal Edinburgh Hospital for Sick Children.

DRANSFIELD, C. M., F.R.C.S.: orthopædic surgeon, Ashton and District Infirmary and Children's Hospital.

FINLAY, H. V. L., M.B. Edin., M.R.C.P.E., D.C.H.: pædiatrician, Hillingdon County Hospital, Middlesex.

NICHOLSON, W. F., M.B.E., M.A., M.D., M.CHIR. Camb., F.R.C.S.: asst. surgeon, Manchester Royal Infirmary.

SCOTT, P. D., M.A., M.D. Camb., D.P.M.: psychiatrist (part-time) in public-health department for duty at L.C.C. remand homes.

ZOOB, MAX, M.D. Lond., M.R.C.P.: first assistant, cardiological department, Royal Free Hospital, London.

University College Hospital, W.C.1:

NICHOLSON, HOWARD, M.D. Lond., M.R.C.P.: asst. physician.

SODDY, KENNETH, M.D. Lond., D.P.M.: asst. physician, department of psychological medicine.

TREDGOLD, R. F., M.A., M.D. Camb., D.P.M.: asst. physician, department of psychological medicine.

Hampstead General and North-West London Hospital:

MARTIN, A. J., O.B.E., M.R.C.S., D.PHYS.MED.: physician i.c. physiotherapy department.

WILLIAMS, A. E., B.SC., M.B. Wales, F.R.C.S.: surgeon to out-patients.

Children's Hospital, Birmingham:

ASTLEY, ROY, M.B. Birm., D.M.R.: asst. radiologist.

CRABTREE, N. L., F.R.C.S., D.L.O.: asst. aural surgeon and laryngologist.

General Hospital, Northampton:

Asst. consultant surgeons:

LAMBLEY, D. G., B.SC., M.B. Lond., F.R.C.S.

TAYLOR, E. E. T., M.A., B.M., M.CH. Oxfd, F.R.C.S.

Diary of the Week

JULY 11 TO 17

Monday, 12th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2

5 P.M. Mr. Norman Capener: Orthopædic Appliances.

6.15 P.M. Dr. H. G. Epstein: Some Aspects of Physics in An thesia.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1

8.30 P.M. Dr. Arthur Proctr, Prof. R. J. V. Pulvertaft: Nat Defences and Disorders of the Respiratory Tract.

EDINBURGH POST-GRADUATE BOARD FOR MEDICINE

3.30 P.M. (Anatomy lecture theatre, University of Edinburgh) Prof. A. C. Frazer: Fat Digestion and Absorption.

Tuesday, 13th

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.1

5 P.M. Dr. J. W. Trevan, F.R.S.: Curare and Curarimim Drugs. (Bertram Louis Abrahams lecture.)

ROYAL COLLEGE OF SURGEONS

5 P.M. Mr. Ronald Furlong: Injuries of the Wrist and Carpus.

6.15 P.M. Dr. Ronald Jarman: Chemistry of Common An thetics.

Wednesday, 14th

ROYAL COLLEGE OF SURGEONS

5 P.M. Mr. A. N. Birkett: Fractures of the Cervical Spine.

6.15 P.M. Dr. B. L. S. Murtagh: Avoidable Accidents in An thesia.

Thursday, 15th

ROYAL COLLEGE OF SURGEONS

5 P.M. Prof. T. P. MCMURRAY: Derangements of the Knee-joint

6.15 P.M. Dr. Ronald Woolmer: Diagnostic and Therapeuti Uses of Anæsthetics.

EDINBURGH POST-GRADUATE BOARD FOR MEDICINE

4.30 P.M. Sir Jack Drummond, F.R.S.: Practical Significance of War-time Experience in the Field of Nutrition.

Friday, 16th

ROYAL COLLEGE OF SURGEONS

5 P.M. Prof. Andrew Jackson (Philadelphia): Growth and Development from the Clinical Aspect of Orthodontics. (Charles Tomes lecture.)

ASSOCIATION OF CLINICAL PATHOLOGISTS

9.30 A.M. (University, Sheffield, 10.) Opening of two-day scientific meeting.

Saturday, 17th

NUTRITION SOCIETY

10.30 A.M. (1, Wimpole Street, W.1.) Conference on the Nutriti of Athletes.

Births, Marriages, and Deaths

BIRTHS

ATKINSON.—On June 29, at Redhill, the wife of Dr. Henry Atkin —a daughter.

BALL.—On June 28, at Vellore, India, the wife of Dr. J. Ball—a son.

BALL.—On July 4, in London, the wife of Dr. Keith Ball—a son.

BEATTIE.—On June 20, in Liverpool, the wife of Mr. W. M. Beat F.R.C.S.—a son.

BISHOP.—On June 28, at Bristol, the wife of Dr. Geoffrey Bish— a daughter.

BROWNE.—On June 26, at Newcastle-on-Tyne, the wife of Pr R. C. Browne—a daughter.

DEVLIN.—On June 27, at Falmouth, the wife of Dr. H. R. T. Devli —a daughter.

FARR.—On June 25, at Mwanza, Tanganyika, the wife of Dr. A. G. Farr—a daughter.

LIGHT.—On June 26, at Burnham-on-Crouch, the wife of Dr L.H.B. Light—a son.

OLIVER.—On June 28, at Norwich, the wife of Dr. W. A. Oliver, M.B.E.—a son.

OSBORNE.—On June 28, at Chalfont St. Giles, Bucks, the wife of Dr. A. S. Osborne—a son.

READ.—On June 30, the wife of Dr. A. M. Read—a daughter

TRETHOWAN.—On July 3, in London, the wife of Dr. W. H. Tretho —a son.

WALKER.—On June 24, at Barnsley, the wife of Dr. M. M. Wal —a son.

MARRIAGES

DICKSON—DAWSON.—On June 26, at Grendon Underwood, H Harper Dickson, M.B., to Elisabeth Dawson.

GIBBONS—DAVIES.—On June 10, at New Tredegar, Mon., Ch Cecil Gibbons, L.M.S.S.A., to Marion Cale Davies.

KUNKLER—HAILEY.—On June 26, Peter Bertrand Kun M.R.C.P., to Pamela Hailey.

MACRAE—CREED.—On July 3, in London, Alastair Douglas Ma M.B., to Ena D. Creed.

MAIR—ORDE.—On June 26, at Blewbury, Robert George M M.B., to Nancy Elizabeth Cecilia Orde.

DEATHS

CONNOP.—On June 30, at Hatch Beauchamp, Somerset, Har Connop, M.A. Camb., L.R.C.P.E., major, R.A.M.C. (T.) retd

COOKE.—On June 28, Martin Alfred Cooke, O.B.E., T.D., M.R.C.

FLEMING.—On June 27, in Edinburgh, Archibald Nicol Flem D.S.O., colonel, I.M.S. retd., aged 78.

HEGGS.—On July 1, in Jersey, Thomas Barrett Heggs, M.D. Ab D.P.H., aged 68.

SMITH.—On June 28, in Jersey, Frank Addinsell Smith, M.D. L D.P.H., lieut.-colonel, I.M.S. retd., aged 78.

MOVEMENT OF THE DIAPHRAGM AFTER OPERATION*

JOHN HOWKINS

M.D., M.S. Lond., F.R.C.S.

ASSISTANT OBSTETRIC AND GYNÆCOLOGICAL SURGEON,
ST. BARTHOLOMEW'S HOSPITAL, LONDON

DURING the late war many Servicemen presented hemselves for elective operation the indication for which was the only lesion in an otherwise fit man. Their espiratory systems, apart from the indiscreet use of obacco, were as good as the average for their age-roup of 20–40 years. Despite this good physique, nd every effort to minimise the use of tobacco, chest omplications after clean hernia operations were umerous, and it was in an effort to discover the cause f this high complication-rate that the present work was undertaken. All Service surgeons were worried by this problem. The primary concern was to investigate chest omplications after operation for hernia, and this xplains the preponderance in this series of these cases which are such notorious offenders. A number of other operations and some extra-abdominal operations were ncluded to act as controls.

The types of operation or the conditions for which hey were performed were as follows:

MacArthur's unilateral herniorrhaphy ..	134
Bilateral herniorrhaphy	1
Femoral herniotomy	3
Appendicectomy—cold and recurrent cases ..	18
Piles, anal fissure, and other anal conditions..	19
Hydrocele	6
Varicose veins	3
Cystoscopy	3
Pilonidal sinus excision..	2
Minor surgery of the hand	2
Circumcision	2
Excision of lipoma	2
Thyroidectomy (non-toxic adenoma) ..	1
Excision of tuberculous glands in neck ..	1
Mastectomy	1
Exploration of gunshot wound of neck ..	1
Brodie's abscess of femur	1
Total	200

he material was standardised as far as possible, and y case was premedicated in the same way, with nopon ’ gr. 1/3 and scopolamine gr. 1/150. No post-ative respiratory depressants were used, except in operations on the anal canal and 1 thyroidectomy. toperative discomfort was treated with simple drugs, as aspirin and bromide, and it is here opportune raw attention to the unnecessary and excessive use pium and its derivatives as a postoperative routine. use is seldom indicated, and its selective action on the iratory centre undoubtedly depresses diaphragmatic ursion. The anæsthetic agents used were, of necessity, ous, but spinal anæsthesia preponderated, because as intended to show that the use of a non-inhalation sthetic is no insurance against postoperative pul-ary complications. Though this fact is well recognised anæsthetists, some surgeons still do not realise that al or local anæsthesia is as great an offender as er, as shown by the following figures:

Anæsthetic	*No. of cases*	*No. with diminished diaphragm movement*
Heavy spinal	113 ..	100
Light spinal	14 ..	11
Pentobarbitone gas-oxygen	41 ..	25
Pentobarbitone gas-oxygen plus ether	19 ..	11
Local (with P.G.O. or without).. ..	13 ..	11
Totals	200	158

Technique.—Twenty-four hours before operation the patient was taken in a wheeled chair to the X-ray department, and it was carefully explained to him what he was expected to do. His coöperation was secured by encouragement and a frank explanation of the investigation. His vital capacity and chest expansion were measured after several practice runs. This expenditure of trouble was considered to be important since low morale and non-coöperation easily vitiate the result of such an experiment.

The chest expansion was measured with a tape placed at the level of the lower border of the sternum, and represented the maximal expansion of which the patient was capable. Vital capacity was measured with a portable spirometer, and here again the patient was encouraged to produce the maximal effort. The movements of the diaphragm were measured by placing the patient behind a fluorescent screen, with the screen touching the anterior chest wall. A small tube aperture was used with the patient in the erect position. On deep inspiration the position of the mid-point of the dome of the diaphragm was marked on the screen, a similar mark being made on full expiration. The mean of several observations was taken.

The erect position was used here, but for future work the supine position is recommended for observing the diaphragm after operation. It is more comfortable for the patient, and in this position the diaphragm has a slightly greater excursion, which is therefore more easily measured. It is not generally realised that a patient can be screened efficiently through most mattresses.

RESULTS

Diminished Movement of Diaphragm

In the 200 cases observed the lower limit of normal excursion was 1·5 cm. and the upper 10 cm. This latter figure was exceptional and only occurred in good physical specimens such as air-crew personnel and athletes. The average excursion was 5 cm. In 158 cases there was a diminution of 1 cm. or more:

Site of operation	*No. of cases*	*No. with diminished movement of diaphragm*
Abdominal parietes	162 ..	149
Extra-abdominal operations	38 ..	9
Totals	200	158

Of these, 31 had postoperative chest complications. and of 42 showing no diminution of movement 2 had chest complications. In 83 cases there was a diminution of 2 cm. or more, 24 of them exhibiting chest complications. In 36 there was a diminution of 3 cm., 16 having chest complications.

Diminished diaphragm movement	*No. of cases*	*No. of cases with chest complications*
No diminution	42 ..	2 (5%)
1 cm. or more	158 ..	31 (20%)
2 cm. or more	83 ..	24 (29%)
3 cm. or more	36 ..	16 (44%)

There is therefore some connexion between the incidence of diminished diaphragmatic movement and the chest-complication rate, and this connexion is explicable in two ways: (1) the diminution of diaphragmatic movement encourages atelectasis, which may or may not lead to an infective process and pneumonitis; or (2) the atelectasis precedes the diaphragmatic changes, and is the cause and not the effect of them. It is impossible to say which comes first, but one observation in this series permits a tentative suggestion—namely, that the radiological evidence appears before the clinical signs; and that, in some cases showing diminution of diaphragmatic excursion, chest complications were expected and did arise before there was actual clinical evidence of any lesion in the lungs. This agrees with Stringer's (1947) conclusion. He investigated the incidence of atelectasis in 55 cases after partial gastrectomy. The first signs appeared radiologically at four hours in 5 cases, and at twenty-four hours in a further 6. He concluded that clinical signs were absent, slight, or misleading,

nterian lecture delivered to the Royal College of Surgeons of England on Jan. 30, 1947.

Figs. 1-5—Superimposed picture of the diaphragm in inspiration and expiration: (1) erect; (2) supine; (3) prone; (4) sitting; and (5) lying on right side. The level on expiration has been emphasised with dotted lines.

Figs. 6 and 7—Unabsorbed gas under diaphragm after abdominal section: (6) on eighth postoperative day; (7) on seventeenth postoperative day.

and that radiography alone could establish an early diagnosis of atelectasis.

The relationship of the site of the operation to the side of the diaphragm in which movement was diminished was investigated in 149 cases, which showed a diminution of diaphragmatic movement after abdominal operation. It was found that the diaphragm was affected on both sides in 92 cases, on the same side as the operation in 42 cases, and on the opposite side in 15 cases. Thus the diminution of movement was not confined to the side of the operation wound. This disagrees with the findings in a small series of cases published by Rees-Jones (1941) and is an argument against a purely local reflex.

Reduction of Vital Capacity

Vital capacity was reduced to some extent after most of the operations, though in 15 cases it was actually increased. This was probably a false reading, owing to a better performance being obtained as the result of practice. The percentage reduction was least in the extra-abdominal cases and more notable in the herniæ. Many patients said they could not obtain a full respiratory excursion because of pain in their abdominal wound. The reduction varied from 5 to 50% or even more in a few cases. Big reductions in vital capacity were noted in cases developing postoperative lung complications, of which there was both clinical and radiological evidence. Not all cases, however, showing diminished vital capacity had a concomitant diminution of excursion, and vice versa. This observation, which seems at first sight a paradox, is explicable as follows: if the diaphragm is not adequately performing its allotted function, there is a compensatory overaction by the thoracic muscles of respiration, and vice versa. These observations agree with those of previous observers. Chest expansion, which is at best a crude method of estimating vital capacity, showed a parallel reduction with reduced vital capacity.

The clinical application of these findings is that breathing exercises which move the thorax do not necessarily move the diaphragm, though if combined with abdominal exercises they are more likely to achieve this aim. Breathing is a complex mechanism involving thorax, abdomen, and diaphragm.

Postoperative Chest Complications

In this series were 33 cases of postoperative chest complication. The definition of this term is subject to criticism, but any patient who exhibited fever, cough, and sputum was considered to have developed a postoperative chest complication. Since these patients were being screened as a routine, there was ample opportunity to pick out any radiological evidence of pulmonary pathology, and 11 cases showed changes not present preoperatively. These were observed by serial screening and radiograms until complete resolution. The change most often observed was partial or complete atelectasis of the lower zones; apical changes were never observed in this series. In 4 of these cases pneumonic consolidation developed. Many cases which showed the signs of postoperative chest complications had persistently clear lung fields. This atelectasis-rate of 5·5% agrees with the findings of other workers (Dripps and Deming, 1946). The low pneumonia-rate is explicable by the age-group of the patients.

MOVEMENT OF THE DIAPHRAGM

Anatomically the diaphragm is a complex structure with a mixed embryological pedigree. It is developed from a fourfold origin, the ventral part from the septum transversum, the dorsal from the mesentery, and the dorsolateral from the pleuroperitoneal membranes, and a peripheral part from the mesoderm of the body wall. This last part retains its nerve supply from the lower six thoracic nerves which it shares with the muscles forming the abdominal parietes. The main motor nerve of the 'aphragm is the phrenic, and it is questionable if the ower thoracic nerves have any share in the motor nnervation of the diaphragm. Their presence, however, ust be of some anatomical significance and certainly plains the close interrelationship of the diaphragm id the abdominal muscles. This close coordination etween the diaphragm and the intercostal and abdominal all muscles almost certainly depends on the central echanism, the respiratory centres of the brain stem nd the descending fibres of the spinal cord. In dogs nilateral section of the phrenic nerve leads to complete nd ultimate atrophy of all muscle-fibres on that side Schlaepfer 1926). The peripheral costal part of the iaphragm arises from the inner surfaces of the costal artilages and adjacent portions of the lower six ribs, nterdigitating with the transversus abdominis muscle n an intimate relationship. The sensory and motor erve supply of the abdominal parietes is derived from he lower thoracic nerves, and action of these muscles in reathing is complementary to the diaphragm, in that they ix and depress the lower ribs and compress the abdominal iscera against the under surface of the diaphragm.

In man the abdominal viscera exert a negative pressure on the under surface of the diaphragm in the erect osition, and this pressure is to some extent countercted by the postural tone of the diaphragm and the onic contraction of the abdominal wall muscles and the pelvic diaphragm. This is well illustrated by the lower position which the diaphragm occupies after a long lebilitating illness, when the tone in these muscles is educed.

The practical application of these facts is that the nspiratory and expiratory levels of the diaphragm vary with varying combinations of the factors influencing the position of the diaphragm. When the body is erect, there is a maximal negative pressure and the diaphragm is low; when it is supine, there is a release of negative pressure and the diaphragm rises (Barclay 1930, Adams and Pillsbury 1922).

ARIATIONS OF DIAPHRAGM POSITION WITH CHANGE OF POSTURE

Position	Movement of diaphragm	Level of upper border of diaphragm	Distance from marker at D 9 (cm.)	
			Right	Left
Erect (fig. 1)	Inspiration	L 1	12·50	13·00
	Expiration	D 12	8·75	10·00
	Excursion		3·75	3·00
Supine (fig. 2)	Inspiration	D 12	9·50	10·50
	Expiration	D 11	5·00	6·25
	Excursion		4·50	4·25
Prone (fig. 3)	Inspiration	D 12	10·50	12·25
	Expiration	D 11	5·50	7·50
	Excursion		5·00	4·75
Sitting (fig. 4)	Inspiration	D 12, L 1	11·25	12·50
	Expiration	D 12	8·75	10·00
	Excursion		2·75	2·50
Lying on ight side (fig. 5)	Inspiration	Lower D 12	11·25	10·00
	Expiration	Upper D 12	5·00	10·00
	Excursion		6·25	nil
Lying on left side	Inspiration	Upper D 12	10·00	11·25
	Expiration	Mid D 11	8·75	6·25
	Excursion		1·25	5·00

An attempt has been made to reproduce radiographically the alteration in position of the diaphragm with change of posture and to measure this. Certain errors are inescapable. Lead skin-markers move with postural changes as the skin is pushed up or pulled down, and even vertebral levels are misleading. When the tube is centred on the level of the diaphragm in the mid-position between expiration and inspiration, the divergence of the X rays is appreciable at full excursion, and this distortion can only be overcome by orthodiagraphic measures. Hence the radiograms shown in figs. 1–5 represent at best a rough and uncorrected picture of the true levels of the diaphragm, a skin-marker and the upper border of the ninth dorsal vertebræ being the base-line. The patient was a Cockney labourer in good physical condition, and measurements (see table) are in centimetres from the tip of the dome of each half of the diaphragm.

This table, which is fairly typical and in agreement with previous work (Butler and Dana 1928, Howard 1924), illustrates the following points:

(1) The right hemidiaphragm lies about 1·25 cm. higher than the left.

(2) The total excursion of both hemidiaphragms is the same.

(3) The diaphragm is highest in the supine and prone positions, and lowest when in the standing or sitting position.

(4) The total excursion is greatest, by 1·25 cm., in the supine and prone positions, when compared with the erect, and least of all, by 2 cm., in the sitting position compared with the supine.

(5) When the patient is lying on one side, the diaphragm pivots about the spine, the upper hemidiaphragm moving but little, the lower moving considerably.

CLINICAL APPLICATIONS

The clinical applications of these observations is clear. Patients after operation can be encouraged by alteration of posture to increase the range of movement of their diaphragm, and to influence the differential expansion of various parts of the lung, whereas the converse of absolute immobility encourages diaphragmatic stasis and its consequent evils. The sitting position is the least advantageous, and therefore Fowler's position is a bad postoperative one.

Since the abdominal musculature and the abdominal contents play so important a part in the movement of the diaphragm, it is obvious that anything which restricts the freedom of movement of the abdomen also affects the diaphragm. Immobilisation of the abdominal muscles owing to pain, trauma, or constricting binders and dressings undoubtedly diminishes movement of the diaphragm and vital capacity. The application of a tight binder to the abdomen of a man who has not undergone any operation can reduce his vital capacity by 30% (Churchill and McNeil 1927, Head 1927).

The presence of free gas in the abdomen, which to some extent occurs in any operation involving incision of the peritoneum, is another factor which embarrasses the diaphragm. Gas under the diaphragm after a laparotomy attains a considerable volume and takes a long time to disappear. Fig. 6 depicts a large collection of gas under the right hemidiaphragm on the eighth postoperative day. Fig. 7 shows that the gas is still present on the seventeenth day, though its volume is diminished by four-fifths. Complete absorption in some cases probably takes a month.

DEVELOPMENT OF PULMONARY COMPLICATIONS

A curious feature of postoperative pulmonary complications is their predilection for the lung bases, and in the past this has been explained by gravitation of unexpectorated bronchial secretion, inhibition of the coughing mechanism, and failure of ciliary action. Viscidity of the bronchial secretion owing to dehydration and overdoses of atropine encourages bronchial retention. If this argument is carried a step further, complete blockage of a bronchus by a viscid plug leads to absorption of the contained air and atelectasis. The stage is now set for a pneumonitis, and it is a mystery why pneumonitis is not more commonly encountered. It behoves us as surgeons to attack this pathological sequence at its inception and not at its conclusion, and the following are a few suggestions:

(1) *Full and adequate pulmonary ventilation* can be achieved by free movement of the patient in bed, or better still by early ambulation, which provides an incidental benefit in counteracting venous stasis and reducing the danger of thrombosis and embolism originating in the deep veins of the calf and leg muscles. Three actors operate against early postoperative ambulation:

(*a*) The patient's subjective fear of pain. This can be overcome by good morale, and the following case is an illustration. A Canadian rear gunner of a Halifax bomber had had a MacArthur herniorrhaphy. He was up in a chair on the first night, went to the hospital cinema on the fifth day, was discharged on the tenth, was given seven days' sick leave, and on the seventeenth day went over Germany in an operational sortie and shot down an enemy night fighter.

(*b*) The fear of the surgeon that his suture lines will not hold. This fear is groundless if proper technique and interrupted sutures are used. For the timid surgeon the use of stainless steel wire is recommended.

(*c*) The diehard traditions of the past and reverence for the magic numbers—i.e., clips out on the fifth or seventh day, tension sutures on the tenth or fourteenth, up on the eighteenth, and out on the twenty-first.

The part played by the abdomen in respiration must not be forgotten. Restriction of this important respiratory muscle must not be tolerated by cumbersome and uncomfortable dressings. The traditional use of the tight many-tailed abdominal binder is a particular menace. This antiquated device achieves little that it is intended to and much that it should not. It decreases the vital capacity by 30%; restricts movement of the diaphragm; travels up to the axilla, pulling on the stitches in its journey, unless anchored by an unhygienic perineal extension; and requires constant adjustment, with the temptation to take a glance at the wound to see if it is all right. Moreover, it and its attendant handmaiden, the generous pad of cotton-wool, make the patient hot and uncomfortable, and cause local sweating about the wound. If a surgeon wants to seal a wound he can do it with collodion, Whitehead's varnish, or 'Mastisol,' all of which stay put. It is time that the binder was abandoned.

(2) *Attention to Postural Drainage of the Lung.*—If the base is the worst drained part and ciliary action is impaired, the proper postoperative position is certainly not sitting up but lying flat or even with the foot of the bed raised. Better still, the patient should lie first on one side and then on the other. Any clinician who has treated a case of bronchiectasis by postural drainage knows this. Figs. 1–5 should convince the most sceptical that such postural movement is salutory to the diaphragm. The adoption of a statuesque attitude should be absolutely banned, and back-rests and donkey pillows studiously avoided. Fowler's position has already been attacked with some vitriol by other writers, and this is both timely and proper. Physiotherapy can play a very useful part, and this was extensively used by the R.A.M.C. in the war. To be of real benefit it must start before the operation, and patients should be taught to breathe correctly, so that they will have had practice in their postoperative exercises when they are called on to perform them. The secret of success in postoperative exercises is little and often, and not a long single session that leaves a patient exhausted for the rest of the day. Such exercises should start as soon as the patient has properly recovered from his anæsthetic, and should be graduated. Another method of moving the diaphragm and expanding the lung is to place the patient in a Both respirator for twenty-four hours after operation. This experiment was performed by Mushin and Faux (1944), who placed twenty-four abdominal operation patients in the respirator for twenty-four hours. Their communication demonstrates the feasibility of the idea, though the figures are too small to prove its therapeutic value as a prophylaxis against respiratory complications.

(3) *The avoidance of respiratory depressant drugs* has already been mentioned.

(4) *Tobacco* has been arraigned as a predisposing factor in postoperative chest complications, and there is no doubt that heavy smokers incur a fivefold greater risk than do total abstainers. Absolute abstention before elective operation, even for a few days, is a small price to ask and, if explained, will usually be accepted.

(5) *The infective element* can be reduced by never performing an elective operation in a patient with an infection of the upper respiratory tract, and by the avoidance of gross infection, by rigid isolation, between patients in a surgical ward. One small point is often overlooked in inhalation anæsthesia—namely, the proper sterilisation of face-pieces, rubber tubing, and breathing-bags between the apparatus and the patient. I doubt if this is often, if ever, properly performed to obtain the standards of full asepsis. Here is an unexplored reservoir of pathogens which deserves the attention of bacteriological and clinical investigators (A. M. Boyd, personal communication).

SUMMARY

Irrespective of anæsthetic used, the diaphragm after operation shows a diminution of movement.

The vital capacity is diminished in a parallel manner.

The diminution of movement of the diaphragm and the diminution of vital capacity vary in different cases, and may reach complete immobility of the diaphragm and a loss of vital capacity up to 60%.

The site of the operation has some relation to the amount of diminution of movement of the diaphragm, which is more notable after operations on the abdominal parietes than after operations elsewhere.

The greater the diminution of movement of the diaphragm the higher the incidence of chest complications.

Suggestions are made for the improvement of excursion of the diaphragm and vital capacity after operation, with special reference to posture and lung drainage.

I wish to thank Dr. P. M. F. Fraser, Dr. T. M. Prossor, Squadron-Leader H. Shepherd, Squadron-Leader D. Raeside, Dr. G. W. Pimblett and the radiological department of St. Bartholomew's Hospital, and Dr. H. Jungmann and the radiological department of the London Jewish Hospital for help with the radiological work; Prof. Sampson Wright for criticisms and suggestions; Air Commodore W. A. S. Duck, my old commanding officer, and Air Vice-Marshal Sir Stanford Cade, my senior surgical consultant in the R.A.F., with whose permission this work was done; and the many nursing sisters in the P.M.R.A.F.N.S. and the R.C.A.F. and R.A.F. radiographers for splendid coöperation in handling the patients.

RAPID DETERMINATION OF URINARY PREGNANEDIOL

METHOD SUITABLE FOR ROUTINE CLINICAL USE

UNIVERSITY OF EDINBURGH

THE Guterman (1944, 1945) qualitative test for urinary pregnanediol, based on the quantitative procedure developed by Astwood and Jones (1941) and Talbot et al. (1941), has been widely used for the early diagnosis of pregnancy and for prognosis in threatened abortion. Though there is some measure of agreement that the method may be useful in the prognosis of threatened abortion (Guterman 1946, Bender 1947, 1948, Merivale 1948), opinions on its value in the diagnosis of pregnancy are sharply divided. Guterman (1944, 1945) and McCormack (1946) have claimed an accuracy as great as that of the Friedman method; on the other hand, Reinhart and Barnes (1946) and Merivale (1948) have reported high percentages of both false positives and false negatives. In our opinion their unsatisfactory results are possibly due partly to technical deficiencies of the method, some of which are avoidable.

The Guterman test depends on the detection, by means of a colour reaction with sulphuric acid, of an amount of pregnanediol in 100 ml. of morning urine which is stated to correspond approximately to an excretion of 6–8 mg. of the steroid per 24 hours. Guterman considers a pregnancy test to be positive if this amount of pregnanediol or more is detected in the urine during amenorrhœa. Morrow and Benua (1946) have, however, observed "false positive tests for pregnancy" in the luteal phase of the menstrual cycle, and have pointed out at, since there may be a considerable overlap between e lower levels of pregnanediol excreted during early regnancy and the higher levels excreted during the tter half of the menstrual cycle, there is a danger of btaining false positive reactions in cycles prolonged by te ovulation. This criticism seems to be valid; but, rovided no reliance is placed on positive reactions obtained ithin a short time of an apparently missed period, he danger of diagnosing a delayed or prolonged luteal hase of the cycle as a pregnancy should not be serious.

Reinhart and Barnes (1946) criticise the method on ather similar grounds, pointing out that "a test which s not accurate in the face of vaginal bleeding is of estricted value as a diagnostic aid in hospital practice." Though this is doubtless true, we feel that their further tatement that "the source of error lies not in the nterpretation of the colour reaction but in individual ariations in the metabolism of progesterone, both in the regnant and the non-pregnant woman" cannot pass nchallenged. They seem *to* have overlooked the ossibility that a not inconsiderable source of both ositive and negative errors may lie in the technique of he stages in the method preceding the final colour sessment, and it is at least possible that they have ver-emphasised the importance of individual variations progesterone metabolism. The methods hitherto sed for studying the excretion of pregnanediol during he menstrual cycle and early pregnancy are insufficiently ccurate to show whether there are considerable individual ariations in the extent to which progesterone is reduced o pregnanediol in non-pregnant and pregnant women.

A general criticism that can be justifiably made of the Guterman method is that a quantitative significance has been attached to the results of a qualitative test. Attempts have been made by several workers to make the test quantitative rather than qualitative by examining the colour spectrophotometrically instead of visually. Such attempts, however, must necessarily fail in their object, since the test is carried out on an unknown fraction of the 24-hour urine output, and since, as recently shown by Sommerville et al. (1948), the procedure used for purifying the extracted pregnanediol is likely to give low and erratic results when applied to urine containing less than about 20 mg. of the steroid per 24 hours.

It seems clear that the value of pregnanediol determinations for diagnosis requires careful reinvestigation with the aid of a method more nearly quantitative and less open to criticism on technical grounds than is the Guterman procedure. The method of Sommerville et al. (1948), which has been shown to be reasonably accurate at levels of pregnanediol* excretion above about 2 mg. per 24 hours, would be suitable for such an investigation but is somewhat too laborious and time-consuming for routine use. Accordingly an attempt has been made to develop a procedure combining the speed and simplicity of the Guterman method with certain of the technical improvements made in the original Astwood and Talbot procedures by Sommerville et al. (1948). The method developed permits of the reasonably accurate quantitative determination in less than 3 hours of the pregnanediol in 100 ml. of urine, provided that the level of excretion is above about 5 mg. per 24 hours. It will probably be less liable than the Guterman method to give erratic results at low levels of pregnanediol excretion, but like the latter it

* Unpublished work by Sommerville and Marrian has shown that *allo*pregnane-3(α), 20α-diol, as well as pregnane-3(α), 20α-diol, is determined by this method. In this paper the term "pregnanediol" is used to designate the mixture of both stereoisomers that is present in urine.

TABLE I—ÆTIOLOGY AND MORTALITY OF 100 CASES OF BRAIN ABSCESS

Source of abscess	No. of cases	Died	Case-mortality (%)
stoid infection	40	16	*40*
'emporal lobe	22	8	
'erebellar	18	8	
racogenic (bronchiectasis, empyma, or lung abscess)	20	13	*65*
astatic from "other sources" boils, carbuncles, cellulitis, infecive endocarditis, &c.)	11	2	*18*
ntal-sinus infection	10	1	*10*
etrating wounds and infected ompound fractures of skull ..	10	5	*50*
'ections of face, scalp, and skull..	7	2	*28*
erative infection of tumour cavity	2	0	*0*
Total	100	39	*39*

Several factors contribute to the high mortality of oracogenic abscesses. The patient is often already hausted by a severe thoracic infection, and the addition any further focus of sepsis adds to the strain. More *portant, however,* is *the fact that the stupor* and mobility which are common symptoms of brain abscess nd to reduce or even eliminate coughing and active pulsion of secretions from the lung. With this failure the pulmonary excretory mechanism the infection nds to spread rapidly through the lungs and the atient may even drown in his own secretions. Furthermore, the brain abscess is usually a complication of a *ntinuing* and chronic infection of the lung, and even the cerebral abscess is dealt with successfully there is lways the risk of another one developing as long as the ing or pleural infection persists. The problem thus ecomes something like that of dealing with intracranial etastases from lung cancer. Until the introduction of enicillin it was well-nigh insoluble. Now, however, not nly can the brain abscess often be successfully treated, ut, as we shall show, the thoracic infection can in some ases be subsequently eradicated by operation.

The thoracogenic abscess is usually multilocular, but he main mass is often single and discrete, and in only of our 20 cases were there multiple abscesses scattered hroughout the brain. This figure is slightly more favourble than that reported in other communications—for xample, in the collected figures of Collis (1944) there vere 63 multiple foci out of 153 cases of abscess. The bscess mass is usually in an accessible situation. Of the 6 cases in which it was single, the abscess was situated the distribution of the middle cerebral artery on the nvexity of the brain; 12 were above the sylvian sure in the frontoparietal region and 4 were in the mporal lobe. Elkington (1939) called attention to fact that metastatic tumours usually develop at the ction of grey and white matter, and this seems to be e of abscesses as well. In only 1 of the cases of multiple ess was there a deep-seated lesion and this was in ptic thalamus. In another case of multiple thoraco- brain abscesses a small abscess in the brain stem suspected, but since this patient recovered the ne lesion was not verified.

Bacteriology

available bacteriological data of 18 of our cases, rised in table II, show that the majority were due nisms which are sensitive to penicillin.

so many were pure infections is somewhat surn view of the mixed flora which may be found in pulmonary sepsis. Indeed, the incidence of mixed ions in this series is considerably lower than McFarlan (1943) found in a series of brain abscesses due to various causes; he found mixed infections in 14 of 48 cases of all varieties of brain abscess. This question is important because some of the organisms may be sensitive to penicillin or sulphonamides and some not. If, in dealing with the abscess, the brain is contaminated by the resistant organism another abscess or a fatal meningitis may result. Actinomyces and gram-negative organisms are especially dangerous, but it is interesting that in 3 cases in which gram-negative organisms were found in films the cultures were sterile.

It should also be noted that in all except 2 cases the brain abscess was the only focus of infection outside the chest. In one there were metastatic abscesses in the thigh, breast, and back, and in the other in the perinephric space. In 1907, Cameron made a similar observation and contrasted it with the frequency with which blood-borne abscesses from other sources (boils, carbuncles, infected wounds, &c.) were multiple. In our own series of 10 metastatic abscesses from other sources than the chest, 2 had obvious multiple abscess in addition to the brain abscess.

Technique of Treatment

In our experience the most effective method is to treat brain abscesses in such a way that they can eventually be dissected out. Such dissections require that the abscess should have a capsule thick enough to withstand reasonably careful handling during operation. The formation of such a capsule takes from five to eight weeks, by which time the abscess is really a chronic one; and the patient must be kept alive until this chronic stage is reached.

In most varieties of abscess this can usually be accomplished by repeated aspirations, though in some cases a decompression may be necessary, as advocated by Vincent et al. (1937). But in thoracogenic abscess aspirations are often difficult and ineffective because the abscesses are usually multilocular, their purulent contents are thick, and it may be impossible to remove enough pus to lower the intracranial pressure adequately, or to do so on more than one occasion. Moreover, the indication for further aspirations is often stupor or impending coma, and there may be several such phases in the process of tiding over the abscess from the acute to the chronic stage. Although periods of stupor may have no untoward consequences in other cases, patients with thoracogenic abscess respond badly because of the adverse effect on the pulmonary condition, as has been set out above. For these reasons we regard thoracogenic abscesses as generally unsuitable for the type of treatment which aims at radical removal in the chronic encapsulated stage.

TABLE II—BACTERIOLOGY OF 18 CASES OF THORACOGENIC ABSCESS

Findings	No. of cases	Film	Culture

ABLE I.—ÆTIOLOGY AND MORTALITY OF 100 CASES OF BRAIN ABSCESS

Source of abscess	No. of cases	Died	Case-mortality (%)
Mastoid infection	40	16	40
Temporal lobe	22	8	
Cerebellar	18	8	
Thoracogenic (bronchiectasis, empyema, or lung abscess)	20	13	65
Metastatic from "other sources" (boils, carbuncles, cellulitis, infective endocarditis, &c.)	11	2	18
Frontal-sinus infection	10	1	10
Penetrating wounds and infected compound fractures of skull ..	10	5	50
Infections of face, scalp, and skull..	7	2	29
Operative infection of tumour cavity	2	0	0
Total	100	39	39

Several factors contribute to the high mortality of thoracogenic abscesses. The patient is often already exhausted by a severe thoracic infection, and the addition of any further focus of sepsis adds to the strain. More important, however, is the fact that the stupor and immobility which are common symptoms of brain abscess tend to reduce or even eliminate coughing and active expulsion of secretions from the lung. With this failure of the pulmonary excretory mechanism the infection tends to spread rapidly through the lungs and the patient may even drown in his own secretions. Furthermore, the brain abscess is usually a complication of a *continuing* and chronic infection of the lung, and even if the cerebral abscess is dealt with successfully there is always the risk of another one developing as long as the lung or pleural infection persists. The problem thus becomes something like that of dealing with intracranial metastases from lung cancer. Until the introduction of penicillin it was well-nigh insoluble. Now, however, not only can the brain abscess often be successfully treated, but, as we shall show, the thoracic infection can in some ases be subsequently eradicated by operation.

The thoracogenic abscess is usually multilocular, but he main mass is often single and discrete, and in only 4 of our 20 cases were there multiple abscesses scattered hroughout the brain. This figure is slightly more favourible than that reported in other communications—for xample, in the collected figures of Collis (1944) there vere 63 multiple foci out of 153 cases of abscess. The bscess mass is usually in an accessible situation. Of the cases in which it was single, the abscess was situated the distribution of the middle cerebral artery on the nvexity of the brain; 12 were above the sylvian sure in the frontoparietal region and 4 were in the mporal lobe. Elkington (1939) called attention to fact that metastatic tumours usually develop at the ction of grey and white matter, and this seems to be e of abscesses as well. In only 1 of the cases of multiple ess was there a deep-seated lesion and this was in optic thalamus. In another case of multiple thoraco- brain abscesses a small abscess in the brain stem suspected, but since this patient recovered the ne lesion was not verified.

Bacteriology

available bacteriological data of 18 of our cases, rised in table II, show that the majority were due nisms which are sensitive to penicillin.

so many were pure infections is somewhat surn view of the mixed flora which may be found in pulmonary sepsis. Indeed, the incidence of mixed ions in this series is considerably lower than McFarlan (1943) found in a series of brain abscesses due to various causes; he found mixed infections in 14 of 48 cases of all varieties of brain abscess. This question is important because some of the organisms may be sensitive to penicillin or sulphonamides and some not. If, in dealing with the abscess, the brain is contaminated by the resistant organism another abscess or a fatal meningitis may result. Actinomyces and gram-negative organisms are especially dangerous, but it is interesting that in 3 cases in which gram-negative organisms were found in films the cultures were sterile.

It should also be noted that in all except 2 cases the brain abscess was the only focus of infection outside the chest. In one there were metastatic abscesses in the thigh, breast, and back, and in the other in the perinephric space. In 1907, Cameron made a similar observation and contrasted it with the frequency with which blood-borne abscesses from other sources (boils, carbuncles, infected wounds, &c.) were multiple. In our own series of 10 metastatic abscesses from other sources than the chest, 2 had obvious multiple abscess in addition to the brain abscess.

Technique of Treatment

In our experience the most effective method is to treat brain abscesses in such a way that they can eventually be dissected out. Such dissections require that the abscess should have a capsule thick enough to withstand reasonably careful handling during operation. The formation of such a capsule takes from five to eight weeks, by which time the abscess is really a chronic one; and the patient must be kept alive until this chronic stage is reached.

In most varieties of abscess this can usually be accomplished by repeated aspirations, though in some cases a decompression may be necessary, as advocated by Vincent et al. (1937). But in thoracogenic abscess aspirations are often difficult and ineffective because the abscesses are usually multilocular, their purulent contents are thick, and it may be impossible to remove enough pus to lower the intracranial pressure adequately, or to do so on more than one occasion. Moreover, the indication for further aspirations is often stupor or impending coma, and there may be several such phases in the process of tiding over the abscess from the acute to the chronic stage. Although periods of stupor may have no untoward consequences in other cases, patients with thoracogenic abscess respond badly because of the adverse effect on the pulmonary condition, as has been set out above. For these reasons we regard thoracogenic abscesses as generally unsuitable for the type of treatment which aims at radical removal in the chronic encapsulated stage.

The introduction of penicillin has opened a new chapter in the treatment of brain abscess. If the infecting organism is sensitive to penicillin, we have a measure of control over the primary source of infection, whether it be in the lung, mastoid, frontal sinus, or elsewhere, and if the infection does extend to the brain it is our impression that it does so rather less catastrophically in patients treated with penicillin systemically than in the days before we had this agent. Penicillin and sulphonamides are powerful allies in the treatment of the meningitis which may result from leakage of the abscess during its development or from accidental contamination of the field during an operation for its removal. In suitable cases penicillin injected into the abscess cavity at the time of aspiration may render it sterile, and in the process of tiding over an acute abscess to the chronic stage we make a practice of injecting penicillin into the cavity after each aspiration.

The evidence for the potency of penicillin in combating intracranial infections is so abundant that the possibility of treating acute abscesses by radical methods is being explored. In one of our cases (case 1) an abscess was sucked out by open operation when it was only ten days old, the resulting cavity being dusted with penicillin-'Sulphamezathine' powder and filled with a solution of penicillin. Le Beau (1946) has reported 17 such cases (3 of them thoracogenic) with recovery in 14. Such operations are less "anatomical" than those for the removal of a chronic encapsulated abscess, in that it is necessary to suck out pus and infected-looking brain until normal white matter is reached, and consequently more cerebral tissue is sacrificed than in the removal of a chronic abscess. This is important when, as often happens, the abscess is situated in an eloquent part of the brain. Some of the total functional deficit may be due simply to pressure and œdema around the abscess, but most of it is due to permanent cerebral damage, and however they are treated the survivors often show a considerable degree of permanent weakness, sensory loss, aphasia, or loss of the visual field. This is in contrast to other types of abscess, such as those due to mastoid or frontal-sinus disease, in which residual disabilities are minimal.

With these advances in the management of brain abscess, the focus of interest now centres on what can be done to the primary thoracic lesion to prevent re-infection of the brain. That re-infection may occur is shown by the following case (R. I. no. 19741).

In June, 1941, a man of 28 developed a left-sided pneumonia followed by empyema. This was treated by aspiration, rib-resection, and drainage, and on Nov. 18 a modified thoracoplasty. The chest continued to discharge, and on Nov. 22 he began to have focal epileptic attacks involving the left side of the body, followed by a rapidly progressive left hemiplegia. A ventriculogram revealed an abscess in the right frontoparietal region and it was aspirated through a burr-hole on Dec. 16. There was some improvement, but the onset of coma and incontinence two days later called for further treatment, so a decompression was made over the abscess. This brought about considerable improvement in his general condition, but the decompression area bulged and became so tense that we feared it would burst. Temporary relief could be obtained by repeated lumbar punctures and the patient was kept alive by this means until Jan. 8, 1942, when it was judged that the abscess was at least forty-seven days old and should be sufficiently encapsulated to be dissected out. A large multilocular abscess mass weighing 120 g. was extirpated from the right frontoparietal region. The patient improved generally and the wound healed normally. Two weeks later signs of an abscess in the left temporal region appeared and this was treated by aspiration and decompression for six weeks, after which we extirpated an abscess mass in the left temporal lobe as large as that which had been removed from the right hemisphere. He died three weeks later with yet a third abscess in the left frontal lobe. It was known that the abscesses in the left hemisphere developed after the one in the right hemisphere because the original ventriculogram had shown that the left hemisphere was normal.

This case emphasises the risk of the continuing chest infection. Had it been possible to arrest this before the second and third abscesses developed, the patient's life might have been saved. In the 2 cases to be described next, the pulmonary lesion was such that it could be dealt with radically after the brain abscess had been extirpated.

CASE 1

Chronic bronchiectasis. Left cerebral abscess, treated by excision in acute stage. Pneumonectomy. Recovery. (R. I. no. 10835.)—A man, aged 21, was admitted on Jan. 18, 1946. He had been in another hospital for six weeks suffering from an acute exacerbation of chronic bronchiectasis which he was known to have had for three years. The infection seemed to be resolving satisfactorily but on Jan. 12 he had a focal sensory attack in his right arm followed by considerable weakness of the right arm and leg. In the next two days he had further attacks of the same nature, each leaving him with rather more weakness than before, so by the time he was admitted his right arm and leg were completely paralysed. The right side of his face was not affected and there was no aphasia or hemianopia. He had very little headache, the optic discs were normal, and the spinal fluid was normal in pressure and content. While under observation he became more drowsy and by Jan. 21 the spinal-fluid pressure had gone up to 240 mm. water though the fluid was still normal on analysis. Radiography of the skull revealed no abnormality. There was extensive advanced bronchiectasis in the right lung.

By Jan. 22, ten days after the onset of the cerebral infection, he was deeply comatose and it was clear that desperate measures were justified. Under local anæsthesia a left lateral flap was reflected. The dura was tense, and before it was opened the right ventricle was tapped and 12,000 units of penicillin instilled. On opening the dura the convolutions in the upper part of the left bolandic region were seen to be broad and pale, with a slight brownish-yellow discoloration in an elliptical zone 6·5 cm. from before back by 5 cm. from side to side. The arachnoid was divided around this zone and immediately beneath the cortex a large multilocular abscess was encountered. It had no definite capsule, though in places there were patches of toughness doubtless due to thickening of the leptomeninges in the sulci. The abscess mass was sucked out until normal-looking white matter was encountered. This made a large cavity lined by œdematous white matter, but the brain was quite slack and it was possible to see a considerable part of the superolateral surface of the left hemisphere which appeared to be normal. As the cavity was inevitably contaminated, it was dusted with penicillin-sulphamezathine powder and 20,000 units of penicillin in solution was left in it. The dura was closed, the bone flap replaced, and the scalp closed without drainage. The pus from the abscess yielded anaerobic streptococci in films and culture.

The wound healed normally and at the end of three weeks the spinal fluid was normal. A transient aphasia cleared up by the end of a week after operation, but the patient was left with complete paralysis of his right arm and leg. The leg subsequently recovered to the point where he was able to get about quite comfortably though the arm remained virtually useless. His chest condition remained quiescent as his general state improved, but since there had been repeated acute exacerbations of the lung infection, a further one of which might be fatal or cause another brain abscess, it was felt that his best chance rested in removal of the infected lung. The pulmonary condition was accordingly assessed and it was found that there was a chronic and extensive saccular type of bronchiectasis confined to the right lung.

On May 30 a dissection pneumonectomy was performed, the lung being very adherent to the chest wall. The patient made an uneventful recovery, and his vital capacity within six weeks of operation was equal to the preoperative figure. When last seen in November, 1947, he was training in leather-work at a rehabilitation centre. He had had no further trouble with his chest. The right leg was spastic but he could walk easily for long distances. The right arm had improved to some extent, but it was still so stiff and weak that it could only be used for gross purposes.

Pathologically the lung showed gross inflammatory changes associated with bronchiectatic saccules. There was considerable fibrosis, and in one area there was a large scar which was regarded as being the possible seat of a healed abscess. In this area there was thrombosis and recanalisation of vessels. The possible significance of this finding and of the density of the pleural adhesions will be discussed later.

As a matter of interest it should be recorded that a brother of this patient had died of a brain abscess following an empyema.

CASE 2

Chronic bronchiectasis. Multiple metastatic abscesses. Right parietal abscess treated by excision. Pneumonectomy. Recovery. (R. I. no. 41226/45.)—A woman, aged 28, suffered from bronchiectasis dating from childhood, presumably beginning with an attack of "pneumonia" at the age of 7. She had been in hospital several times with signs of pulmonary suppuration such as fever, cough, and purulent sputum, and in July, 1945, a small left-sided basal empyema was recognised and drained at the Harefield Thoracic Unit. Closure of this cavity was slow since it was presumably secondary to the underlying lung infection.

During the next three months suppuration developed in the chest wall and spread into the submammary region, where it was incised and drained. Shortly afterwards an abscess appeared on the back of the right thigh; this was presumably of metastatic origin and was also drained.

In spite of this continued suppuration the patient's general health remained fairly good until Jan. 29, 1946, when she had an epileptic attack with loss of consciousness, ushered in by a sensation of bright lights. In the next three weeks she had 3 similar fits, complained of a good deal of headache, and noted a haziness in the left field of vision.

On admission, on Feb. 20, 1946, she was alert and coöperative and looked very well, despite discharging sinuses in the left chest and in the left breast and right thigh. From the chest *Proteus vulgaris* and diphtheroids were cultured, and from the thigh *Staph. aureus*. She was afebrile, the pulse-rate was 80 per min., and the respiration-rate 20 per min. Neurological examination revealed no papillœdema, but there was a lower quadrant defect in the left homonymous visual field. There was no sensory or motor disturbance in any part of the body, except that the left plantar response was extensor. The spinal-fluid pressure was 100 mm. water. The fluid contained 60 mg. protein per 100 ml. and 2 cells per c.mm. Radiograms of the skull were normal, but those of the chest showed opacity of the lower half of the left lung field.

She was kept under observation, and 25,000 units of penicillin was given intramuscularly every three hours. She continued to complain of headache, and repeated examination of the visual fields showed that the lower quadrant defect was extending to involve the upper quadrant. There thus seemed no doubt that there was a progressive lesion in the right parieto-occipital region, and an abscess secondary to pulmonary sepsis seemed the most likely diagnosis.

By March 12 it was estimated that the abscess was at least six weeks old and that radical extirpation should be possible. A ventriculogram on this date confirmed the localisation and at operation a multilocular abscess mass was dissected out of the parieto-occipital region. The main mass had a tough wall, but one small loculus ruptured and a few drops of pus escaped into the field, which was technically contaminated. No organisms were seen in films and cultures were sterile. The cavity in the brain was dusted with penicillin sulphamezathine powder and 20,000 units of penicillin in solution was left in it. The left ventricle was also treated with 12,000 units of penicillin at the beginning of the operation. The dura was closed, the bone flap replaced, and the scalp closed without drainage.

The wound healed normally, but her convalescence was marred by an aseptic meningitis, the fluid containing up to 5000 cells for ten days after operation. No organisms were seen in films, nor were any cultured. The meningitis was treated with sulphadiazine by mouth and 12,000 units of penicillin intrathecally every day for sixteen days. By April 1 she was free from symptoms, the fluid contained 60 mg. protein per 100 ml. and 28 cells per c.mm. Neurological examination revealed only a lower quadrant defect in the left homonymous field of vision.

The relation between cerebral and chest conditions had been carefully borne in mind, and it was decided that removal of the septic pulmonary focus should be undertaken with the minimum of delay. Accordingly she was returned to the Harefield Thoracic Unit, where a bronchiectatic left lower lobe and lingular process were removed on April 18. The lung was firmly adherent, but was removed without incident by dissection of the areas described, and convalescence was uneventful. When she was discharged in June, 1946, the chest had healed and lung expansion was adequate.

Thereafter she remained well, except that she had two epileptic attacks in the first six months after the cranial operation. These were mild and did not recur in the ensuing fourteen months.

It should be noted that in this case pulmonary lobectomy was performed within four weeks of the excision of the brain abscess and that the patient withstood these two major interventions remarkably well. This probably illustrates the maximum of our present therapeutic powers, but has demonstrated that a combined thoracic and neurological attack is a possibility, and should be considered wherever practicable.

If the brain abscess develops during the course of a chest infection which is going to resolve spontaneously or respond to radical treatment, the problem is simply that of dealing with the brain abscess and is similar to that of a metastatic brain abscess from "other sources" (table I), in which the mortality in our cases has been 18%. Cases 3 and 4 illustrate this point.

CASE 3

Lung abscess following gastrectomy for pyloric stenosis. Spontaneous resolution. Left frontal brain abscess treated by excision. Recovery. (R. I. no. 21249/44.)—A man, aged 37, was admitted to the Radcliffe Infirmary on Jan. 12, 1944. In February, 1943, he had a partial gastrectomy for pyloric stenosis following a perforated duodenal ulcer ten years before. The operation was done under local anæsthesia, and convalescence was interrupted by sepsis in the abdominal wound and an abscess in the left lung. The lung abscess was studied by repeated X rays and it appeared to resolve spontaneously, presumably by discharging into a bronchus and being coughed up. The abdominal wound healed, and he was discharged from hospital on March 31, 1943, still having a good deal of cough and sputum. This improved steadily until by September, 1943, he had no cough or sputum and X-ray films of the chest were normal.

In June, 1943, he began to have focal epileptic attacks involving the right arm and leg, and during the next five months a considerable right hemiplegia developed and he began to suffer from headache. These symptoms led to his admission to hospital, when it was found that he had bilateral papillœdema, a slight nominal aphasia, and a profound right hemiplegia maximal in the arm. There was slight sensory impairment of cortical type in the right arm and leg. The visual fields were full. The spinal-fluid pressure was raised, and the cerebrospinal fluid contained 50 mg. protein per 100 ml. and 20 cells per c.mm., mostly lymphocytes.

The presumptive diagnosis was chronic abscess in the left rolandic region due to the previous lung infection. A ventriculogram confirmed the localisation and at operation on Jan. 25, 1944, the abscess was dissected out intact. On section it was bilocular, and its walls were up to 0·4 cm. thick. The pus was creamy and yellow; no organisms were seen in films and cultures were sterile, but histological preparations showed a profuse branching mycelium resembling aspergillus. Convalescence was uneventful. The wound healed normally and six days after operation the spinal fluid had reverted to normal (35 mg. protein per 100 ml., 2 cells per c.mm.). The aphasia cleared up, and the right arm and leg improved considerably to the point where he could get about quite comfortably. He remained well in the ensuing three and a half years.

CASE 4

Chronic empyema. Left frontal abscess, treated by aspiration and excision. Recovery. (R. I. no. 37322/45.)—A man, aged 45, came under observation on Feb. 2, 1945. He had a chronic right-sided empyema, which was drained on Jan. 8, 1945, and the chest condition seemed to be progressing favourably. On Jan. 28 he had a small hæmoptysis and later in the day a generalised epileptic attack. Apart from some headache there were no sequelæ. Next day he had a succession of attacks ushered in by aphasia and characterised by turning of the head and eyes to the right side, and clonic movements of the right side of the face and right arm and leg. These attacks left him with some aphasia and considerable weakness down the right side of the body. The hemiplegia became more marked and by Feb. 7 it was virtually complete. The aphasia likewise became more profound and he gradually became more stuporous. The spinal-fluid pressure was 210 mm. water, and the fluid contained 120 mg. protein per 100 ml. and 14 cells per c.mm.

An abscess in the posterior part of the left frontal lobe was suspected and a burr-hole was made over the supposed site on Feb. 7; 30 ml. of pus was aspirated from a depth of 4·5 cm. in the frontal lobe, and 10,000 units of penicillin and 3 ml. of thorotrast were instilled into the cavity. Subsequent X-ray films showed the abscess occupying the upper and posterior part of the frontal lobe. The pus contained numerous gram-negative rods, but cultures were sterile.

The patient improved steadily after aspiration. Although some aphasia persisted he became quite alert and rational and the headache disappeared. The hemiplegia likewise cleared up. Successive X-ray films showed that the abscess remained about the same size—i.e., it did not shrivel up as happens with some abscesses which resolve simply with aspiration. On April 6, when it was reckoned that the abscess was about ten weeks old, an osteoplastic flap was reflected and the chronic thick-walled abscess was dissected out intact. Convalescence was uneventful and he was discharged from hospital on April 20 free from symptoms or signs except for a very slight speech defect, apparent on formal tests. The chest wound meantime had healed and he remained well up to the time of the last follow-up in February, 1948, apart from occasional epileptic attacks which do not interfere with his work as a labourer.

These cases were favourable because the chest infection had cleared up or responded to treatment by the time the brain abscess was dealt with, and there was no risk of further trouble from the chest. The next 2 cases emphasise the risk of the continuing chest infection, and show that the chest infection carries its own risk as well as that of recurring or multiple metastatic infection in the brain.

CASE 5*

Diffuse actinomycosis with widespread pulmonary lesions. Intensive penicillin therapy. Right cerebral abscess treated by excision. Recovery. (R. I. no. 59241/46.)—A man, aged 46, began, in July, 1944, to complain of vague abdominal symptoms associated with an intermittent temperature. In January, 1945, a pelvic mass pressing on the rectum was detected, and a laparotomy in March revealed a tumour adherent to the rectum. The abdominal incision healed with the formation of three sinuses, from which in July actinomyces were isolated. In November he was critically ill with an abscess of the liver which ruptured into the lung and caused a diffuse bronchopneumonia. There was a fæcal fistula in the abdominal wound, and an ulcer on the tongue and one in the left arm. He was treated with large doses of penicillin (a million units a day) and there was some general improvement. In December there was a relapse in the chest condition, but again this settled down.

On June 9, 1946, the patient complained of headache for the first time. Two days later he had a focal sensory attack in the left hand and arm, and next day there was a nearly complete paralysis of the left arm and considerable weakness of the left leg. These signs remained more or less stationary but he continued to complain of headache.

He was admitted to the Radcliffe Infirmary on June 28, at which time there was slight bilateral papillœdema and a considerable left hemiplegia, maximal in the arm. There was some loss of sensibility of the cortical type in the left hand but no defect in the visual fields. He was in good general condition, however, and could get about with a hemiplegic gait. Radiograms of the chest showed changes compatible with hepatic and pulmonary actinomycosis. The erythrocyte-sedimentation rate was 60 mm. in 1st hour and the white-cell count was 8000 per c.mm. Actinomyces were found in the sputum. A ventriculogram showed a depression of the central part of the body of the right ventricle and a slight displacement to the left side. At operation on July 6 a subacute abscess was removed from the right frontoparietal region. The abscess measured about 2 cm. in diameter, had a very thin wall and contained about 6 ml. of pus. Some diphtheroids were seen in films, but cultures of the pus were sterile and histological examination of the abscess revealed no evidence of actinomyces.

The postoperative period was stormy for a few days because of exacerbation of the chest infection, but he gradually recovered from this. The cranial wound healed normally, and, though there was a transient increase in the hemiplegia, this too recovered to the level which obtained before operation—i.e., he was left with considerable weakness of the left arm and slight weakness of the leg, but he could get about quite easily. The headache cleared up and the papillœdema disappeared. He returned to work and remained well apart from an isolated epileptic attack. When last seen twenty-two months after operation he still had bronchiectasis for which he was receiving daily inhalations or injections of penicillin, but his general state was satisfactory.

This case is significant because it suggests that massive doses of penicillin have a favourable influence on actinomycosis; by the time the abscess was excised the patient had already received some 300 million units of penicillin. Secondly, it shows that the brain abscess may be due to only one of several organisms responsible for the chest infection. The preoperative diagnosis in this case was an actinomyotic abscess or granuloma, because it was known that the patient had pulmonary actinomycosis. But in fact the abscess was due to a gram-negative bacillus which presumably was only one of several which might have been found in the lung. As the chest infection still persists, this patient would be in a somewhat hazardous state if he did not continue to have penicillin.

CASE 6

Chronic bronchiectasis. Metastatic abscesses in left loin and left temporal lobe. Drainage of perinephric abscess. Excision of brain abscess. Recovery. Death later from acute pulmonary infection. (R. I. no. 64710/46.)—A man, aged 66, was admitted to the Radcliffe Infirmary on Nov. 8, 1946, with aphasia and a right hemiplegia. He had had bilateral bronchiectasis for about twenty years, and for nine months before admission his cough had been more troublesome and the sputum more abundant, and there had been occasional small hæmoptyses. Nevertheless he could do his work as a grocer until six weeks before admission, when he had a fit (which was not reliably observed) and began to suffer from severe headache. Three weeks before admission he began to have difficulty in expressing himself. A week later he complained of severe pain in the left loin and within a few days a swelling appeared. This was incised and drained, and it had practically healed by the time he was admitted to the Radcliffe Infirmary. The pus from the abscess yielded *Staph. albus* on culture. In the week before admission a profound weakness of the right side of the body developed and the speech difficulty was more pronounced.

On admission he was conscious but drowsy, and there was gross aphasia affecting all aspects of the speech function. He was thin and pale, and had a loose cough with purulent sputum. The optic discs were normal, but a complete right homonymous hemianopia could be demonstrated. There was a nearly complete right hemiplegia affecting face, arm, and leg, and he seemed to resent painful stimuli less on the right side of the body than the left. The spinal-fluid pressure was 165 mm. water, the fluid contained 250 mg. protein per 100 ml. and 300 cells per c.mm., 92% being polymorphs. Radiograms of the skull showed no abnormality except slight displacement of the pineal gland to the right. The chest showed advanced bilateral bronchiectasis on radiography and clinical examination.

The presumptive diagnosis was abscess of the left cerebral hemisphere due to the bronchiectasis. An arteriogram showed that the abscess was in the left temporal lobe. A left lateral osteoplastic flap was reflected on Nov. 12 under local anæsthesia. The dura was tense, and before it was opened the right ventricle was tapped and 12,000 units of penicillin was instilled. The convolutions in the left temporal lobe were broad and pale, but the abscess was not presenting on the surface as is often the case. The middle temporal convolution was excised and this exposed the capsule of the abscess. There proved to be two main loculi with walls thick enough to allow them to be dissected out intact, but there were also many smaller loculi clustered about these which had to be removed with the sucker. The cavity was thus contaminated with pus from these smaller loculi. The suction was continued until normal white matter was reached, and this meant removing the interior of almost the entire temporal lobe. The cavity was dusted with penicillin sulphamezathine and 20,000 units of penicillin was instilled. The dura was closed completely, the bone flap replaced, and the scalp closed without drainage.

---

* This case is to be reported at length elsewhere.

Convalescence was uneventful. The wound healed normally, nd ten days after operation the spinal-fluid pressure was ormal and the fluid was clear and colourless and contained 0 mg. protein per 100 ml. and 8 cells per c.mm. He was much brighter and more alert, but the neurological abnormalities remained much as before operation. He was got out of bed a fortnight after operation and was discharged on Nov. 29, 946. He remained well for two months, when he got a severe cold and developed bronchopneumonia, which proved fatal within a few days. No autopsy was done, but the physician who attended him said that it seemed to be a straightforward respiratory illness without any evidence of a recurrence of the ntracranial infection.

Discussion

Several points emerge from a consideration of these cases. It is clear that now that penicillin is available the difference between success and failure in their treatment is determined largely by the nature of the chest infection. If a brain abscess develops during the course of a chest infection which is resolving or is likely to do so (as in cases 3 and 4) the outlook should be reasonably good. Such cases are unfortunately rare; in the majority the chest infection is a chronic one unlikely to resolve or respond to conservative treatment, and it continues to menace the patient's life on its own account (as in case 6) besides being a potential source of metastatic abscesses. The elimination of chest sepsis, or at any rate its control by minor surgical and palliative measures, should always be attempted, so that the risk of cerebral infection is minimised. We feel too that the thorough and long-continued administration of penicillin parenterally is a useful prophylactic measure, and that if a cerebral infection does arise in spite of penicillin prophylaxis its virulence will be somewhat lessened, as in case 5.

If the infection is confined to one lung (as in cases 1 and 2) or is otherwise within the scope of radical thoracic surgery, we may reasonably expect a cure, and we feel that in every case of thoracogenic abscess the possibility f a combined attack by the neurological surgeon and he thoracic surgeon should be carefully considered. In many cases advanced bilateral pulmonary disease will mean that there is slight hope of a permanent cure, but n some of these (as in case 5, with bilateral pulmonary actinomycosis) once the brain abscess has been successully treated the patient may continue to lead a useful ife with the aid of penicillin. In others removal of the brain abscess may bring about an unexpected improvement in the chest condition. We feel indeed that every thoracogenic brain abscess should be treated, no matter how discouraging the chest infection may appear to be.

Often the patient is too ill to withstand any major procedure when he first comes under observation; this is usually due to a combination of increased intracranial pressure and an exacerbation of the pulmonary infection. In such cases probably all that can be done is to make a burr-hole over the abscess, aspirate as much pus as can be got out, and hope that this will tide over the crisis and enable a more deliberate attack to be made within a few days when the general condition has improved.

If the circumstances allow deliberate treatment, we would encourage removal of the brain abscess as soon as it begins to produce stupor or respiratory depression, whichever is manifest first. In some cases severe paroxysmal headache is the indication for operation; this is usually the result of a critical rise of intracranial pressure and it may cause death without antecedent stupor or respiratory depression. Neurological deficits are of less importance as indications for operation; thus a patient may have a considerable hemiplegia or hemianopia for days or weeks before there is much headache or any stupor or respiratory embarrassment.

If the abscess is to be removed, precise knowledge of its location is essential. In some cases this will be apparent from the clinical examination; in others arteriography is probably the safest diagnostic procedure since it does not disturb the pressure relationships within the cranium. If this is not available or does not provide adequate information, then ventriculography may be called for, though we regard this as more dangerous in abscesses than in tumours. If the abscess has to be sucked out in the acute stage, the resulting cavity should be treated with penicillin at the time, and the dura and bone flap should be dusted with penicillin sulphamezathine powder. The bacteriology of the abscess should be established as soon as possible so that appropriate chemotherapy and antibiotics can be supplied. The wound should be closed without drainage, as in the case of removal of a chronic abscess or a brain tumour.

In most cases the brain abscess should be dealt with first because it constitutes the more immediate threat to life. Nevertheless, it is important to proceed with the chest operation as soon as possible, and case 2 demonstrates that a patient can tolerate major intracranial and thoracic operations within four weeks of each other. In some straightforward cases the interval may be shorter with advantage; in others it may have to be longer because of complications ensuing on the cerebral operation, such as a bout of meningitis or a temporary exacerbation of the pulmonary infection.

It is worth noting that in most of the successful cases the patient was under observation at the onset of the cerebral infection and that the diagnosis was made in the early stages. We cannot emphasise too strongly that the advent of cerebral symptoms—usually an epileptic attack—in a patient suffering from pulmonary infection calls for immediate neurological diagnosis and observation. Operation may have to be undertaken as an emergency, and if the patient has been in deep stupor or coma for several hours before he can be got into neurological hands his chances of survival are greatly diminished. Cerebral symptoms, such as epileptic attacks, may occur with air-embolism, but in these cases recovery is usually prompt, there are no residual neurological defects, and the cerebrospinal fluid is normal.

We have produced no definite evidence as to how the infection gets from the chest to the brain, but from the mode of onset and the distribution of the lesions we think that they probably result from embolism. It has been suggested by Collis (1944) and others that there is a retrograde infection along the intercostal veins, thence to the spinal veins, and thence to the cranium. If this was the case we would expect to encounter abscesses en route—i.e., in the spinal cord and posterior cranial fossa—but in fact such lesions are almost unknown. The most cogent argument against the embolic theory is the relative infrequence of metastatic abscesses in other regions than the brain. But this also applies to other blood-borne infections, where the brain may be the only site of abscess formation. The vagaries of embolism are further seen in cases in which there may be embolic abscesses in almost every organ except the brain. The mechanism of the infection is not entirely an academic consideration; in many cases the cerebral infection appears shortly after some minor operation on the chest wall, such as dilating a sinus, and the theory of retrograde infection has this in its favour.

Our chief concern has been with treatment, and we feel that there is now some hope in dealing with this serious complication of chest disease, although we realise that not every case can be cured, and that some of the patients who recover will be left with considerable neurological disabilities.

WEIL'S DISEASE

ANALYSIS OF 195 CASES IN ENGLAND

J. C. BROOM
O.B.E., M.D. St. And.
BACTERIOLOGIST, WELLCOME LABORATORIES OF TROPICAL MEDICINE, LONDON

J. M. ALSTON
M.B. Edin., M.R.C.P.E.
PATHOLOGIST, GROUP LABORATORY, ARCHWAY HOSPITAL, LONDON

THE serological diagnosis of Weil's disease (leptospirosis icterohæmorrhagica) has been carried out in these laboratories for many years, and some of the results have been reported previously (Alston and Brown 1937, Broom and Brown 1943). Between the beginning of 1940 and the end of 1946 samples of blood were received from 195 positive cases and, where possible, the following information was obtained about each patient: sex; age; probable method of infection; presence or absence of jaundice; and recovery or death. Not all these details are available for every patient, but sufficient have been received to make an analysis of interest.

The diagnostic criterion was the agglutination of a formalinised culture of *Leptospira icterohæmorrhagiæ* observed by the microscopical technique described by Schüffner and Mochtar (1926).

Agglutination of leptospiræ by serum from persons who have not been exposed to infection is very rare, even in serum dilutions of 1/10 or 1/30. Artefacts and certain non-specific precipitations are seen with some sera but are readily differentiated from true agglutination by their microscopical appearance. In practice, therefore, any degree of agglutination is regarded as suspicious but, when the titre was 1/300 or less, further samples were examined, where possible, to test for the rise in antibody content which takes place during the disease. This precaution is particularly necessary when the patient's occupation may previously have exposed him to infection.

EPIDEMIOLOGY

Method of Infection.—The prevalence of Weil's disease among coalminers, fish cleaners, and workers in sewers and on the land has long been recognised; so has its occurrence after bathing in canals and stagnant rivers. These associations are all represented in the present series as follows:

Farm workers ..	23 (12 %)	Handlers of food ..	8 (4 %)
Sewer ,, ..	22 (11 %)	Navy personnel ..	2 (1 %)
Fish ,, ..	13 (7 %)	Army personnel ..	47 (24 %)
Coalminers	12 (6 %)	Air Force personnel	8 (4 %)
Bathing	9 (5 %)	Miscellaneous ..	22 (11 %)
Accidental immersion	3 (1 %)	Unknown	13 (7 %)
Working in water ..	13 (7 %)	Total ..	195 (100 %)

Patients who had been working in water are grouped separately because the portal of entry of the infection was probably different from that in the bathers. The group includes men working on bridge repairs, watercress beds, and river drainage and conservancy schemes, where infection through the conjunctivæ and mucosæ of the nose and mouth is unlikely. The miscellaneous group is of special interest because it illustrates some of the diverse conditions in which infection may take place. Leptospiræ shed in rat urine can live for considerable periods in wet surroundings if the reaction is slightly alkaline. Infection may thus occur though there is no direct contact between rat and human, provided that rats can contaminate material which is afterwards handled by man. Persons believed, because of the known presence of rats, to have been infected at work included fishmongers, butchers, waiters, kitchen porters, refuse collectors, sailors, bricklayers, carpenters, motor mechanics, dock labourers, and workers in a factory preparing compressed cattle food. Two other patients had lain in wet ditches as the result of motor-car accidents; two children were apparently infected while playing in rat-infested bombed buildings; one man was an A.R.P. warden; another was in the habit of drinking water from a ditch where rats abounded; and a third worked at a dog-racing track.

Details about patients in the Armed Forces were generally not available, but some of the patients were infected during manœuvres, and others on active service in Italy and Normandy; one was probably infected while lying in a wet ditch tending a wounded man.

A certain piquancy attaches to the case of the ship's stoker who, when asked about possible contact with rats, told how the crew of his ship were in the habit of preparing tea in a large urn kept constantly hot on the galley stove. Water and dry tea were added as required but the spent tea leaves were removed only at irregular intervals. On one of these occasions a rat "boiled white" was found in the debris.

Sex.—The sex-incidence of 189 known cases was males 181, females 8 (4·4%), showing the usual preponderance of males which probably reflects the greater risk of infection in certain predominantly male occupations avocations and does not indicate a real difference i susceptibility. The proportion of females is much higher when the chances of infection are equal for the two sexes. Thus Smith and Davidson (1936) obtained evidence of equal rates among male and female workers handling fish in Aberdeen.

AGE-INCIDENCE OF CASES OF WEIL'S DISEASE AND RECOVERIES AND DEATHS THEREFROM

	Age (years)						
	Up to 15	16–30	31–45	46–60	Over 60	Total	Unknown
No. of cases	12	31	31	21	5	100	95
No. of deaths ..	2	4	4	6	3	19	6
No. of recoveries ..	10	19	22	15	2	68	21

Age.—The accompanying table shows the distribution of cases by age, known for 100 patients. As is to be expected in view of the ætiology of Weil's disease, the very young and the aged are less often affected than those in the prime of life.

Case-mortality.—The final result is known in 114 instances. There were 89 recoveries and 25 (22%) deaths, a very high mortality compared with the 9·4% reported for Holland (Walch-Sorgdrager 1939). During the period covered by our cases, and also in England, Gardner and Wylie (1946) found a mortality of only 8·8%. The two rates are not comparable, however, because Gardner and Wylie assumed the recovery of every patient who was not known to have died, whereas we include only those cases in which the outcome was recorded. If it were calculated on the basis of the total number of cases, the mortality in our series would be reduced t 13%.

The age-distribution of recoveries and deaths in t 87 cases for which it is known is shown in the table.

Jaundice.—Different observers have found the pr portion of cases with jaundice to vary over a wide range. Inada et al. (1916) state that "jaundice is the most striking and constant symptom"; but, also in Ido and Wani (1917) reported that of 56 cases seen d an epidemic 33 (60%) were anicteric. Schüffner (193 noted over a period of years in Holland that the p portion of anicteric cases rose as the annual num of cases increased, suggesting that a more acute a ness of the condition led to the diagnosis of many atyp cases which would otherwise have been missed. Schüff considers that 60% of the total is probably a good estimate of the number of anicteric cases of leptospirosis. In Great Britain Buchanan (1927), describing an outbreak of Weil's disease among coalminers, records that jaundice was present in all 22 patients. Davidson et al. (1934), investigated 15 cases, in 11 of which there was jaundice. On the other hand, Buzzard and Wylie (1947) report 5 consecutive anicteric cases and contrast them with 10 previous cases, 7 with jaundice, treated in the same hospital.

Records are available for 120 cases in our series; jaundice was present in 107 and absent in 13, which makes the proportion of anicteric cases only 10%.

DISCUSSION

The large proportion of jaundice and the high mortality are both outstanding features in this series. The two might be considered to be related, because Walch-Sorgdrager (1939) states that only one fatal anicteric case had been reported in Holland, and certainly all except one of our fatal cases were accompanied by jaundice. It appears from the published reports that jaundice is more often absent when infection takes place during bathing, and only 9 of our patients were infected in that way. Unfortunately, a record is available of only 4, but jaundice was present in all of these 4. When the mode of infection of the 13 anicteric cases was examined, it was found that 2 children had paddled but not bathed in a river known to be infective. The other patients were 4 farm workers, 1 fish worker, 1 tripe-factory lorry-driver, 1 canteen worker, 1 child who played in a bombed building, 2 soldiers whose history is unknown, and 1 schoolgirl with no known contact with rats but who certainly had not been bathing.

There is thus no relation between bathing and absence of jaundice in this series, and some other reason must e sought for our findings. One explanation might e that these are all hospital patients, representing mainly e more severe infections, whereas milder cases are eated at home without the diagnosis being confirmed y serological tests. In this connexion one group of 0 cases is of particular interest. They were all diagnosed y one physician and they form the contemporary part f the series described by Robertson (1946). Of these 0 cases 8 were anicteric as compared with 5 among he remaining 100. The number involved is small, but he difference is very striking, and the probability of btaining such a difference as the result of chance is less han 0·001—i.e., it is statistically significant. Of this ame group 5 patients were females, whereas only 2 ases were diagnosed in females in the remaining 169. In this instance also the probability for a chance result is less than 0·001.

When these findings are considered along with Buzzard and Wylie's (1947) 5 anicteric cases, it seems reasonable to assume that many cases of leptospirosis are missed because they do not present the classical symptoms of Weil's disease, or because the patient was not employed in one of the occupations recognised as carrying a risk of infection.

SUMMARY

Details of sex, age, method of infection, presence of jaundice, and final outcome are analysed for 195 cases of leptospirosis diagnosed by serological tests.

Attention is drawn to the diversity of the occupations and avocations in which infection may take place, and examples are given.

The jaundice-rate and mortality were unusually high. Evidence is adduced which suggests that many cases of leptospirosis are missed in this country.

We wish to thank the many clinicians and pathologists who have provided us with details of these cases.

ACUTE INTESTINAL OBSTRUCTION IN TYPHOID FEVER

F. F. KANE
M.D. Belf., M.R.C.P.I., D.P.H.
MEDICAL SUPERINTENDENT, PURDYSBURN FEVER HOSPITAL, BELFAST

ACUTE intestinal obstruction due to, and arising in the course of, typhoid fever appears to be extremely rare. The following case had unusual features.

CASE-RECORD

A private in the A.T.S., aged 20, was admitted to Purdysburn Fever Hospital on Oct. 8, 1946. She had reported the previous day with a fresh crop of old-standing psoriasis, for which treatment was ordered. That night she developed a severe headache, had a restless night, and felt sore all over. On reporting these symptoms she revealed that she had recently spent two weekends in a neighbouring town where there was an outbreak of typhoid fever. She thus reached hospital with a provisional diagnosis of typhoid about 16 hours after the onset of symptoms—the earliest admission of a case of typhoid in my experience. According to her Army pay-book she had received two injections of T.A.B. during July, 1944.

Investigation.—Temperature 101·4°F; pulse-rate 120 per min.; complained only of headache and shivering. Widal test on day of admission positive only to *Salmonella typhi* (0-specific) to a titre of 1/25; no flagellar agglutination. Sample of stools on same day showed no enteric organisms, but blood-culture gave pure growth of *S. typhi*, subsequently identified as of the phage type recovered from cases in her home town. This positive blood-culture was confirmed by a second culture next day. White-cell count 3300 per c.mm. Marris's test gave a pulse increase of 16 per min.

Course of Illness.—The patient's condition developed along the usual lines of early typhoid, with typical decubitus, and signs in the mouth, tongue, abdomen, and chest. Four days after admission her temperature reached 104·8°F and there was increasing stupor. She was put on a five-day course of intramuscular penicillin and sulphathiazole by mouth. In this course she had 10,000,000 units of penicillin and 42 grammes of sulphathiazole without any arrest of symptoms or signs. On the 8th day of illness, in the middle of this course, she developed a typical typhoid rash, and her spleen became palpable. After an interval of three days the course of penicillin and sulphathiazole was repeated in the same dosage—i.e., 250,000 units of penicillin and 1 g. of sulphathiazole three-hourly for five days. Thus by the 19th day of illness she had had two five-day courses, totalling 20,000,000 units of penicillin and 82 g. of sulphathiazole. Nevertheless there was no diminution in the severity of symptoms or signs. Toxæmia and prostration were well marked, with incontinence of urine and fæces, and deafness and typical typhoid delirium were pronounced. The temperature remained between 102 and 104°F, with pulse-rate 120, blood-pressure 108/66 mm. Hg, and respirations 28 per min.

The stools, thrice previously negative, grew *S. typhi* on the 29th day of illness and remained positive thereafter. The Widal test by the 10th day of illness showed agglutination to *S. typhi* 1/50, flagellar and somatic. By the 37th day the titre

for *S. typhi* was 1/500 and there was no agglutination of *S. paratyphi* or of *Brucella abortus*.

An abscess developed deep in her left thigh from a hæmatoma round the site of penicillin injection, and pus aspirated on the 37th day gave a pure growth of *S. typhi*. This abscess made it difficult to be certain of the condition of the left femoral vessels, and there was a suspicion at this time of thrombophlebitis. The abdomen always seemed well under control, and distension was never a prominent feature. Diarrhœa was at its worst during the third and fourth weeks; thereafter motions were approaching normal in appearance and frequency. There was no remission in the septicæmia. A blood-culture taken on the morning of her 43rd day of illness gave a growth of *S. typhi*.

In the evening of the 43rd day she had a sudden onset of acute abdominal pain without vomiting. She quickly became collapsed. Temperature fell from 103 to 101°F; pulse-rate was 156, and blood-pressure 90/50. Both iliac fossæ were acutely tender but there was no rigidity, no loss of liver dullness, no alteration in chest signs, and nothing abnormal in the alkaline urine. A perforation appeared unlikely, and mesenteric thrombosis was tentatively diagnosed.

Operation.—Laparotomy was performed within three hours of the onset of these symptoms, under ether and gas-oxygen anæsthesia. A right gridiron incision revealed much free serous peritoneal fluid, definitely not intestinal contents. No free gas; cæcum grossly distended. Through this incision only the terminal 12 in. of ileum could be inspected; it was much injected and showed numbers of adhesions to itself and the ascending colon, with areas of peritoneal reaction over typhoid ulcers. A firm peritoneal band between the ileum and ascending colon, which was obstructing the cæcum and terminal small intestine, was divided.

A midline subumbilical incision disclosed a further loop of acutely obstructed ileum produced by a firm peritoneal band running from the antimesenteric border of the ileum to the pelvic colon. This band was divided, but several small omental-ileal adhesions were left untouched. Inspection of the ileum showed no sign of perforation, though there was much evidence of active ulceration. The abdomen was closed without drainage after liberal dusting with sulphonamide powder.

Postoperative Course.—The first twenty-four hours after operation were very difficult, as was to be expected, but then there seemed promise of improvement. The abdominal condition settled quickly, and good motions were voided daily from the 45th day. The chest condition became acute, but in spite of this there was an improvement in consciousness. The patient was given 200 ml. of typhoid serum by intramuscular injection at this stage. Intramuscular penicillin 400,000 units three-hourly and sulphathiazole 1 g. three-hourly by mouth were resumed and continued until death took place quickly from circulatory failure on the 48th day of disease.

DISCUSSION

This case appears unique in its early admission to hospital as typhoid. Admission was decided largely on the history of the patient having drunk milk from a contaminated supply and on symptoms suggesting early infection. The subsequent course of the illness suggests that little benefit had resulted from the T.A.B. inoculation; the clinical picture was that of an unmodified attack.

There was keen disappointment with the response to combined penicillin and sulphathiazole therapy after the decidedly promising results recorded by McSweeney (1946). It is possible that the dosage of penicillin used in this case in the early stages was insufficient; previously Prof. J. W. Bigger (1946) recommended 3,000,000 units a day, but in a personal communication he suggests a dosage of 4,000,000 units daily. Cases from the same source as this patient gave good results on this therapy elsewhere.

With the lowered incidence of enteric infection rare complications are unlikely to be found in modern literature.

Osler and Cole (1902) and Keen (1898) do not mention acute intestinal obstruction in the course of typhoid. Rolleston and Ronaldson (1940) mention non-perforative peritonitis, and Goodall (1928) describes a similar condition with formed apparently by stretching of adhesions due to p of lymph. Curtillet (1939) records a case of perforation at the 17th day of an attack of typhoid in a boy of 7 years, where a loop of terminal ileum was obstructed by its firm fixation in the pelvis, and recovery followed ileostomy and subsequent repair of the fistula.

A more impressive case is that of Alglave (1939) in a female patient of 25 years with an acute onset of abdominal symptoms at the 28th day of typhoid. There was acute crampy abdominal pain with vomiting, and increasing distension. Visible peristalsis was produced on palpation and there was no point of maximum tenderness. Laparotomy two days later disclosed a newly formed peritoneal band between the loop of bowel and the pelvic wall, snaring the ileum and causing the acute obstruction. Division of this band relieved the condition and recovery thereafter was uneventful.

SUMMARY

A case is recorded of acute intestinal obstruction arising in the course of protracted typhoid fever.

The multiple obstruction was caused by peritoneal bands, probably due to stretching of adhesions formed over areas of typhoid ulceration. Division of the bands relieved the abdominal symptoms, but death followed from typhoid septicæmia.

Therapy with penicillin and sulphathiazole was disappointing, but insufficient dosage may explain this.

The patient had a record of T.A.B. inoculation about 27 months before the onset of symptoms, but the course of the illness was severe and unmodified.

I am indebted to Dr. G. F. W. Tinsdale for the bacteriology of the case, and Mr. H. P. Hall for the surgical treatment.

SYRINGOMYELIA TEMPORARILY RELIEVED AFTER SCALENOTOMY

John M. Potter
M.B. Camb.

In the following case of syringomyelia a temporary remission of symptoms followed scalenotomy.

An Anglo-Indian woman, aged 23, had noted four and a half years earlier that while playing the piano her left little finger felt weak. Shortly afterwards she could not straighten it. Six months later the ring finger became similarly affected, and a month after this she began to have a dull tingling ache down the medial aspect of her left arm, passing behind the elbow and down the inner border of the forearm as far as the wrist. The pain was intermittent and not severe, but was aggravated by carrying heavy things or any undue exercise of the arm; it was not aggravated by coughing or sneezing. After a further eight months her attention was drawn t wasting of the left hypothenar muscles. Massage, radia heat, and splinting, had no permanent effect on her disabil and two years after its onset, radiography showing no eviden of a cervical rib, scalenus anticus syndrome was diagnos and a left scalenotomy was performed. (There is no reco of any objective sensory or vascular abnormality in the affected limb at that time, nor has the patient ever noticed any such symptoms apart from the pain.) After this operat all her symptoms were entirely relieved, but the w remained.

Two years and four months later she knocked her shoulder against a cupboard. This produced a similar p which persisted, becoming a little more severe. Two after this injury her left hand became suddenly "cramped while knitting, and afterwards she noticed that her ingers were weak and bent as before; they remained in that condition. Shortly after the injury to her shoulder, whenever he jumped down from a vehicle, landing suddenly on her feet, he felt in her left shoulder blade a jarring pain which, though sharp at first, gradually wore off.

Her general health was good and there were no other symptoms. She had never had any serious illness or injury, and no eye trouble.

I found her an intelligent and genuine person. She gave a lucid unexaggerated history, and was extremely coöperative during examination. She was small, but well-built and looked healthy. There was no deformity or tenderness of the spine. Neck movements were full and painless. The radial pulses were equally palpable and there was no significant variation during neck rotation or shoulder bracing. The movements at both shoulders, elbows, and legs were strong, and the tone was normal in the muscles. The left hypothenar and the medial part of the thenar eminence were flattened, and fasciculation was observed there at intervals. It appeared to be a little increased after the injection of 1 ml. of 'Prostigmin.' There was some weakness of all the left hypothenar muscles, the interossei (notably the medial two), the medial two slips of flexor digitorum profundus, and possibly flexor carpi ulnaris. Froment's thumb sign was positive. In the right hand there was a suggestion of early wasting of the adductor pollicis brevis, but no detectable weakness or fasciculation was observed, and Froment's sign was negative.

Sensory examination revealed dissociated anæsthesia, segmental in distribution but affecting the right side more than the left. On the right, in C8 and T1 segmental areas, there was incomplete appreciation of pinprick and temperature. To a lesser extent pinprick felt dull in T2–T4 segmental areas; and in C4–C7 it was not felt with the same intensity as in C3. On the left, in C8 and T1 segmental areas, pinprick and temperature were similarly affected, but rather less than in the corresponding segments on the right. Here again C3 seemed to be the lower limit of acute sensation to pinprick. Cotton-wool sensation, joint-position sense, and two-point discrimination were everywhere normal, but vibration sense was a little impaired everywhere on the right side below the clavicle. No trophic changes, burns, or scars were seen except the left supraclavicular operation scar. There were no sensory changes in the face.

The right radial reflex was inverted: finger flexion only. The left radial reflex was brisk, with finger flexion. The right biceps reflex was absent; and the left was brisk. The right triceps reflex was normal and the left was absent. Abdominal, knee, and ankle reflexes were normal and equal. The plantar responses were both flexor. Sweating was nduced, and was greater on the left side of the face and forehead than on the right; the upper limbs were affected equally. The pupils and palpebral fissures were equal, and there was no nystagmus. The fundi and cranial nerves were normal. No cutaneous neurofibromata were present.

The blood-count was normal; Hb 84% (Sahli). Blood Wassermann and Kahn reactions were negative.

Lumbar puncture produced clear colourless fluid, rising to a height of 160 mm. There was a brisk rise and fall of 100 mm. on bilateral jugular compression. The cerebrospinal fluid contained 15 mg. of protein per 100 ml.; no cells were present and the Wassermann reaction was negative in the fluid.

Radiography of cervicodorsal spine showed no abnormality, and screening showed good movement of the diaphragm on both sides.

On this evidence there could be little doubt about the diagnosis of syringomyelia.

DISCUSSION

Swank and Simeone (1944) have described a superior, or upper, and an inferior, or lower, type of the scalenus anticus syndrome. In their series of 17 cases, 9 were upper and 8 lower. In the upper it is primarily C6 and C7 nerve-roots that are compressed, and in the lower C8 and T1. The syndrome may be bilateral, and the two types may be combined. These writers believe that the scalenus anticus muscle is the main compressing force, and they noted at operation several factors which they consider important in producing this compression. These were physiological hypertrophy of the muscle and various anatomical abnormalities. Respiratory overactivity and "myositis" were also considered. Ochsner et al. (1935) have cited spasm, as a result of trauma or irritation, as a factor; and Naffziger and Grant (1938) refer to embryological, anatomical, developmental, and occupational mechanisms.

If all these factors are at work, it is reasonable to believe that many people suffer minor degrees of root compression by the scalenus anticus muscle, and that for each person showing the syndrome there may be several in whom this compression is insufficient to produce any obvious interruption of conduction in the nerves.

If a nerve-trunk is compressed at two points along its length, the effect on function, if any, will be a result of the combination of these two forces. Neither of the forces alone may be sufficient to produce symptoms, but together they may do so. In the present case the scalenus anticus may have been an insignificant compressing force until the intramedullary cord lesion higher up started to cause effective pressure on the anterior horn cells of the nerves affected also lower down. If the lower compressing force were removed, as by scalenotomy in this case, one might expect the symptoms to clear until more anterior horn cells were compressed. In this case the symptoms came on again after trauma, which possibly caused a slight hæmatomyelia. It was a chance happening that the cord segments affected were those giving birth to roots liable to scalenus compression (in this case C8 and T1), but presumably it has happened before and will again. In such a case, where the cord lesion cannot be extirpated, I suggest that the relatively minor operation of scalenotomy might provide dramatic, if only temporary, relief from symptoms.

SUMMARY

A case of syringomyelia is described in which the symptoms were relieved for two years and four months by scalenotomy.

An explanation is offered for this result.

Scalenotomy may prove a useful palliative measure in chronic incurable disease affecting any of those segments of the spinal cord which give rise to nerve-roots liable to compression by the scalenus anticus muscle. These roots are C6–8 and T1.

I wish to thank Sir Hugh Cairns for his help in the preparation of this paper.

"... The Royal College of Obstetricians and Gynæcologists has from time to time stated its views on the maternity services to be provided under the National Health Service Act ... We reiterate our conviction that the care of the pregnant woman, whether at home, at the clinic or in hospital, is a responsibility which cannot be discharged with the maximum safety to the two lives at stake if it is shared between different administrative bodies. The importance of full coordination in reducing maternal and infant mortality is so great that the duty of providing a coordinated scheme for *all* aspects of maternity work must be placed unequivocally on one authority at regional board level. ... The college has always advocated that it is desirable to have a list of practitioners who have had experience of midwifery after qualification to be called in for midwives' emergencies under the Act. ... It appears now that any practitioner can undertake maternity work under the Act. He may not necessarily be present at the confinement but will be called upon in an emergency. The principle which the college has always recommended will be discarded if such a practitioner does not possess the experience mentioned above."—Sir WILLIAM GILLIATT, F.R.C.O.G., *Times*, July 9.

Reviews of Books

Anatomy

A. David Le Vay, m.s., f.r.c.s. London: Hodder & Stoughton for the English Universities Press. 1948. Pp. 209. 4*s.* 6*d.*

Mr. Le Vay has provided "as many illustrations as a book of this size will carry," and very good they are. Anatomy, like murder, is not easily brought home in the absence of a body, but this little book does wonders in the way of clear exposition. The general reader, for whom it is primarily designed, may perhaps find himself struggling fly-like in the webs of anatomical terminology, but the nurses and physiotherapists, and even the medical students, to whom it is also commended, will think themselves well treated.

Cineplasty

Henry H. Kessler, m.d., ph.d., formerly chief of amputation center, U.S.N. Hospital, Mare Island, California. Oxford: Blackwell Scientific Publications. 1947. Pp. 201. 35*s.*

The subject of cineplasty is arousing new interest in many countries where efforts are being made to improve the fitment and use of specially designed—and it is claimed more useful—arm prostheses. In this book the history of cinematised arm stumps is ably told and illustrated from the time of the earliest experiments of Riccard in France (1891) and Vanghetti in Florence (1898); and this section, with an account of the functional use and development of the upper extremity, makes an excellent introduction to the subject. The main purpose is to discuss the physiology and detailed anatomy of the arm in relation to the surgery of cineplastic operations. Illustrations of the cineplastic prosthesis suggest that it is unduly complicated and heavy when worn on the various types of cinematised stumps. If cineplasty is to be developed and used, appropriate types of prosthesis must be studied and developed. Nearly all the prostheses are shown with a form of mechanical hand, doubtless chosen for cosmetic reasons. The hand might well be detachable, to permit the attachment of the types of appliance used with ordinary artificial arms. Workers, and those with a hobby in which tools are used, need a few appliances to grasp the tools. These should be quickly and easily interchangeable with the hand. Reablement is given proper emphasis. If a patient knows there is a sphere in which his reduced capabilities can be economically employed it helps not only him but all concerned with his surgery, convalescence, fitment of limbs, and restoration to social life and work. The book is rather over-illustrated, explanatory notes and references being rather too short. The reader would be assisted if photographs were related more exactly in their context.

The Secret Instrument

Dr. Walter Radcliffe, with an introduction by Wilfred Shaw, m.d. London: Heinemann Medical Books. 1947. Pp. 69. 10*s.* 6*d.*

This little book recalls the primitive condition of the practice of midwifery in this country almost to the 18th century. It lay almost entirely in the hands of a number of ignorant women, and the few doctors who did practise it as part of their profession were almost as ignorant and unskilled. Midwifery was frowned on by the physicians of the day and was relegated to the barber surgeons. In the 16th century that great and humane French surgeon, Ambroise Paré, did what he could by establishing a training school for midwives in Paris, but the dangers of difficult labour were by no means overcome. There is indeed a strange irony in the fact that the most wonderful event in human existence—the birth of another life—should be so treated. As Dr. Radcliffe shows, the advent of the Chamberlen family in this country prepared the way for a more scientific approach in midwifery. The disclosure in 1813 of the hidden instruments of Peter Chamberlen revealed how far he had progressed in the evolution of the obstetric forceps now in general use. Before his time, infant mortality was very high and in the difficult cases in which cæsarean section was attempted the maternal mortality was also alarmingly high. Hugh Chamberlen carried on the tradition and indeed showed his belief in his own practice by bringing into the world 18 children of his own. It was not until 1877, however, that Professor Tarnier, of Paris, introduced his axis-traction forceps. This, and the recognition of the pelvic curve, finally led to the obstetric forceps of today. Incidentally the author gives us many interesting side-lights on domestic life in high places in this country during the Stuart period. Dr. Radcliffe does well to emphasise how much we owe to the Chamberlen family.

Médecine de l'aviation

Bases physiologiques et physio-pathologiques. J. Malmejac, professeur de physiologie à la Faculté de Médecine d'Alger, directeur du laboratoire d'études médico-physiologiques de l'Armée de l'Air en Afrique du Nord. Paris: Masson. 1948. Pp. 333. Fr. 12,000.

This synopsis of the work which has been published to date on the physiological aspects of flying will be chiefly of value to the English reader for its very extensive bibliography divided into sections on the basis of subjects and running into nearly 50 pages. Unfortunately much of the more important work in aviation medicine has not yet been published by the Government departments concerned, and Professor Malmejac clearly has not had access to some of the Service reports which have already appeared in English; but the monograph can be recommended to serious students of aviation medicine.

The Organisation and Management *of Hospital* **Stores** (*London:* Faber & Faber. 1948. *Pp.* 105. 15*s.*).—Hospital stores are too often scattered about all over the place, and some harassed stewards, mainly trying to put all their quarts into the pint pots available, may well be grateful for the many practical suggestions contained in this little book, from the authoritative pen of Captain J. E. Stone, the consultant on hospital finance to King Edward's Hospital Fund for London. Captain Stone covers a subject to which increasing attention will be paid in the future administration of hospitals. He steers a skilful course between red tape and extravagance, and hospital management committees and their executives have again cause to thank him.

***Alsos*: *the Failure in German* Science** (London: Sigma Books. 1948. Pp. 258. 15*s.*).—Prof. Samuel Goudsmit here describes the failure of German scientific effort to utilise nuclear physics. A history of a U.S. mission to investigate any possible German "atomic bomb secrets," the book is mainly concerned with the theme that the Germans failed not because of lack of government support but rather in spite of it, the entire blame being laid on German egotism and the Teutonic system of seniority that stifles at birth the ideas of any young genius. Two chapters about "Science and the Gestapo" are irrelevant to the argument. The final chapter, however, is an appeal to the public not to hamper research by allowing useless restrictions to be imposed in a field about which they know nothing; and this plea for a return to internationalism in science is perhaps the only thing that could justify the publication of *Alsos*.

Essentials of Fevers (2nd ed. Edinburgh: E & S *Livingstone. 1948. Pp. 351. 15s.*).—*This little book* has grown appreciably in its second appearance, but it may still be fairly described as a pocket edition. It covers a most surprising range with four concise introductory chapters and a terminal catalogue of some common mistakes in the diagnosis of fevers. Dr. Gerald E. Breen's attempt to compress the essential facts about at least 21 separate communicable diseases into the intervening 246 pages has resulted in a digest which will meet the present examination requirements of the medical student but is perhaps less likely to elevate the study of fevers from the lowly position among the clinical sciences about which he so rightly complains. This condensation also limits the value of the book for the young practitioner. Since the teaching of fevers is nowadays being given additional space in the student's curriculum, it cannot unreservedly be recommended as a standard book, particularly as it contains no single reference to other works. But the racy eminently readable text will be liked by many students, and Dr. Breen's flair for illustration has given this edition 16 coloured drawings, most of which achieve a great deal more than elaborate and expensive photographic processes would have done.

THE LANCET

LONDON: SATURDAY, JULY 17, 1948

Appointments

In the National Health Service how will vacancies in hospital staffs be filled? This is a question of truly fundamental importance to the service, and the answer—though not, we hope, the whole answer—is given in regulations[1] now laid before Parliament.

Under the Act all appointments senior to that of registrar are to be made by the regional hospital board or (in teaching hospitals) by the board of governors. For each vacancy the board will constitute an advisory appointments committee with seven members chosen for the particular task. The committee set up by a regional board will include two members nominated by the management committee of the hospital which has the vacancy, and one or both of these must be doctors. Of the other five members at least four will be medical: two of them must belong to the specialty concerned (one of these coming from outside the board's area), and at least one will be appointed after consultation with the university associated with the board. The intention is that normally the committee shall consist of five professional and two lay members, and the board will itself select one of the seven as chairman. For filling a vacancy in the staff of a teaching hospital the committee constituted by the board of governors will have two members nominated by the university, and one or both of these must be doctors. Of the other five members at least four will be medical: two of them must belong to the specialty concerned (one of these coming from another teaching hospital), and at least one will be appointed after consultation with the hospital board of the region. When a vacancy occurs the board will advertise it in two or more professional journals circulating throughout the country: the advertisement will give information about the nature and duration of the appointment, the remuneration, and the closing date for applications, and will state that canvassing members of the board or committee disqualifies the candidate. The committee will then consider the applications (holding interviews if it thinks fit) and submit to the board a list of persons suitable for the appointment, in order of preference. If the board does not want to appoint any of the persons thus selected it must re-advertise the post. It cannot fill the vacancy in any other way.

Complex though this may sound, it is really quite simple: henceforward all senior medical appointments in all hospitals are to be open to all comers, and the selection will be made in each case by a small and specially nominated expert committee advising the regional board or the board of governors. Casting a bright light into potential holes and corners, the new procedure represents in fact a triumph for those reformers who have long been working to make hospital appointments depend more on merit and less on local influence or acquaintance. The efforts made over so many years to abolish "in-breeding" in the teaching schools gain further support, and an end is made of the parochial methods by which local authorities have too often filled medical posts. Nevertheless the benefit to be gained in general from the new arrangements should not blind us to their possible faults. In one respect, unfortunately, they may prove strikingly inferior to the best existing practice. If their effect is to take the selection of new members right out of the hands of the hospital staff, they may gravely damage the corporate spirit which ought to mean so much in a hospital—a spirit depending not least on free choice of colleagues.

The regulations, it is true, provide for presentation of the "local view"; for the appointments committee is to contain two representatives of the management committee of the hospital in question. But if the medical staff of the hospital do not see the applications or the candidates, how can they form the view that is to be presented? Up to July 4 it was customary in many voluntary hospitals to ask every candidate for an appointment to call privately on every member of the staff, or of a large appointments committee; and though this was a laborious process, for all parties, it was evidence of the importance that some of the most experienced hospitals attach to personal relations. One does not, and should not, lightly choose associates with whom one will have to work for twenty or thirty years, and this is the reason why so many medical committees have taken this part of their duty so seriously and have often been content to devote several hours to the discussion of a single appointment. It is to be feared that, in practice, the new appointments committees advising the boards will not be able to give quite so much time to this work, and this makes it all the more desirable that the hospital staff concerned should have a share in the decision. If they do not bear part of the responsibility they will less cheerfully bear the brunt of mistakes. With any method errors are inevitable, but some of the more painful clashes of personality could certainly be avoided if the medical staff were given an opportunity to see the candidates who have been short-listed by the appointments committee. The committee would do the main work of selection, for which it has the best qualifications; but the medical staff would have a chance, if they thought fit, to explain to the committee—and if necessary to the board—that their own order of preference would, for personal or other stated reasons, be different. Some such arrangements can and should be made within the framework of the new regulations. If, for the sake of administrative simplicity, the boards do not take the trouble to make them, we hope that this inconspicuous but major issue will be raised by the Central Health Services Council in its early neonatal period. One of the ever-present dangers of the service is that too much of value may be sacrificed to mere convenience.

---

Tendon Reconstruction in the Hand

"HERE is something wrong. Excise it!" So runs one of the earliest principles of surgery, and in the development of this attitude the surgery of excision has attained a high level of competence and safety. The stage is now being reached beyond which subtraction from the human frame ceases to be profitable. "We think too much," said Sir JAMES WALTON recently, "of the preservation of life, without considering the quality of the life that is preserved." An encouraging trend of surgery is towards operations that modify function or restore a function that is absent or has been lost. The hand has long remained outside the surgeon's serious interest; and this is not surprising, for the results of intervention have mostly been disappointing. It is strange, nevertheless, that the primary importance of the hand to the patient has not been insisted on, and that the attitude of mind still prevails which will provide an immediate hospital bed and senior surgical attention for an elderly patient with an advanced carcinoma yet requires a young working man with an injury to the hand to be treated by the newly qualified in the casualty department. Such an attitude is no longer permissible, for the results of reconstructive surgery in the hand are now among the most beneficent in surgery. This advance is largely due to two causes—an improved knowledge of the reactions of tissues to injury, and perfections in technique. The atraumatic methods of the plastic surgeon and neurosurgeon are of great value in hand surgery, and it is largely the advances in these two specialties during the last thirty years that have made reconstructive surgery of the hand practicable and effective. Among those who have shared in this advance are CUSHING, JEFFERSON, and GILLIES and his colleagues BLAIR and BROWN, but it is to BUNNELL that we look as the pioneer of the atraumatic method in the hand. By his practice and teaching BUNNELL has shown the surgical world that loss of skin, nerve, tendon, or tendon-sheath in the hand can be repaired and a reconstruction achieved restoring movement and sensibility to man's most important working instrument.

At King's College, Newcastle-upon-Tyne, on June 25, Mr. GUY PULVERTAFT, himself a leading exponent of modern hand surgery, explained the conditions that govern successful tendon reconstruction in the digits, palm, and wrist. He urged the importance of primary wound closure so as to reduce scar-tissue to a minimum; the necessity for early tendon repair, whether at the first operation, as in the palm or at the wrist, or as soon as the wound is united, as in the finger; the need to select the correct procedure for each repair, PULVERTAFT preferring to use a tendon graft to replace a tendon injured in the thecal canal and to suture tendons divided more proximally; the significance of early nerve regeneration in the restoration of function to an injured digit; and the necessity for an exact, atraumatic, and specialist technique. The conditions that make primary tendon reconstruction inadvisable include inadequate operation conditions, crushing of the tissues, and wounds heavily contaminated or with much skin loss or some days old. The operation technique is the basis of success, but as soon as the wound is united active movements are essential, assisted by every art and force of character of the surgeon and physiotherapist. If the tendon unites but movement remains restricted, the tendon may be freed from its adhesions at a later operation and full movement still regained. The results of these procedures are most satisfactory. Full or almost full restoration of movement is the rule when reconstruction is done under ideal conditions by a specialist team.

For the present this work will inevitably develop in surgical centres where the conditions for operation and postoperative arrangements are suitably organised, and where the surgical team has the necessary qualifications for the job. These include an aptitude for minute and scrupulous technique and a sound training in general surgery with extra experience in plastic, nerve, and orthopædic surgery. Such a training and special experience are necessary for any surgeon who aspires to be a master of his craft, and it is better for the surgeon to combine these experiences in himself than that they should be divided between the several members of a team. In the United States hand surgery is now an accepted specialty, to which impetus will be given by the recent formation of the American Society of Surgeons of the Hand. It is unlikely that such a confinement of interest will gain favour in this country. The value to hand surgery of a wide experience in the principles from which it derives is not less than the value of the refinements of hand surgery to general surgical practice. Many surgical units, including several of the new professorial units, have concerned themselves with the problems of the hand as part of their more general work. In every area there should be at least one unit developing the facilities and techniques necessary for reconstructive hand surgery, and ready to disseminate its knowledge and example throughout the area. Only in this way will hands receive everywhere the surgical attention that their importance demands.

The Games

IT is safe to predict that the London Olympic Games will see a large number of previous records broken; for several of the athletes competing have already recorded times or distances better than the 1936 figures, and in any case Olympic performances have improved at every meeting since 1896. Of the 22 major track, field, and swimming events, 16 of the present records were set up in 1936, and the remaining 6 in 1932. The reasons for this trend are both biological and sociological. There have been improvements in the conditions the athlete competes under, in athletic technique, in the population sampling of each country, and perhaps in the general or average physique throughout the world. Of these for better technique and better sampling must have had most effect. Weather conditions vary from one Games to another, and the excellence of the Berlin track cannot have accounted for more than a fraction of the new records made there, though a downright poor track can seriously slow a runner.

It is only in the last twenty years that athletic technique has become stabilised, particularly in the field events, and it still improves steadily or (as in swimming) by spectacular steps. The most phenomenal improvements in performance have been in events where technique is of greatest importance;

uch as the hurdles, the high-jump, and the throws. Athletes now use all the apparatus of slow-motion inematography and time and motion study to control heir style, and the track and field events are settling lown into an applied science of human movement, where a painstaking approach to an ideal will replace ntuitive discovery. After one or two more Olympic Games, however, we may have to rely for new records chiefly on the other sources of improvement How can we find our superman, and how can we improve the whole population so that our athletic genius also reaches new heights? It was the express intention of Baron DE COMBERTIN, the founder of the modern Games, that they should stimulate the spread of athletics through the population of all countries, and this they have done. There remain vast differences in the efficiency of selection from one country to another. Leaving aside the question of professionalism, which only affects directly some of the minor events, class customs still have a strong restraining influence and are seen in their most anachronistic form in the Pentathlon and other purely military events in the Games themselves. The British track and field team has in the past been drawn mostly from the public schools and the Achilles Athletic Club, because outside these the tracks were few and coaches and tradition lacking The situation is changing slowly, as the tradition of separate class activities fades and physical education becomes recognised as a subject worth studying and worth teaching. Selection is most efficient in some parts of the United States, where physical education is an important item in the curriculum of the ordinary school, and where the universities sometimes provide scholarships for students more suited to this type of instruction than to any other. This, rather than the absolute size of the population, largely explains the supremacy of the United States in most events.

But there is another respect in which America is favourably placed. A considerable proportion of American successes have been due to Negro athletes, and in view of the limited opportunities of this group to take part in athletics, there is a widespread feeling that they are, either on the average or in the extreme, superior to the white man in athletic skill. This superiority clearly resides in some aspect of physique. It has been said,[1] for example, that the coloured sprinter under stress shows less tendency than the white to bend outward at the knee, presumably because of a difference in the knee-joint formation or the whole leg leverage system. None of the suggested reasons are very convincing. Some work has been done on the subject,[2] and groups of Olympic athletes have been measured, but nothing very systematic has yet emerged. In general one would expect a sprinter to have powerful legs and a light body, or, in the more precise terminology of SHELDON, a mesomorphic increase in the leg region over that of the rest of the body. Any race requiring not the rapid anaerobic breakdown of large quantities of glycogen but the continuous utilisation of large quantities of oxygen by the muscles calls for a highly efficient cardiovascular system, and in particular highly vascularised muscles. During the brief period of relaxation in the runner's stride enough oxygen must reach the muscles to supply his needs for the ensuing muscular contraction. This type of efficiency perhaps depends on the androgyny or masculine-feminine component of body-build. It is known that the lactic-acid production of women is greater, and hence the concurrent utilisation of oxygen less, than that of men doing an equivalent amount of moderate work; that the performance times of men with high androgyny are worse than those with low; and that androgens have an effect both on skeletal muscle and on the cardiovascular system. To suggest that Negro athletes have a lower femininity component than whites is to go beyond present evidence and to oversimplify the situation, since other athletic feats than running remain to be explained; but the whole subject would well repay further study by the improved means now available.

As for the last of our hypothetical reasons for improvement, in the last fifty years the growth process has been speeded up all over the world, so that adult height and weight are reached earlier than previously; and it is highly probable that adult size has really increased. Both are believed primarily to be nutritional effects, with perhaps further help from the breaking down of genetic isolates. But whether there has been a trend towards increasing muscularity, or towards decreasing androgeny, or in any other direction, is as yet unknown. Meanwhile, putting speculation and explanation behind us, we look forward to a previously unmatched exhibition of grace, skill, and strength.

King Edward's Fund

IN the past King Edward's Hospital Fund for London has perhaps been best known for its grants towards maintenance costs and capital expenditure; and some may ask how its assets, running into several million pounds, are now to be used. The answer was given last week by the Duke of Gloucester, presiding at the annual meeting of the general council at St. James's Palace. He pictured the new functions of this body as those less of a fund than a foundation, on the lines of the Rockefeller Foundation. Nevertheless, the new health service has not relieved the Fund of all maintenance costs; 117 convalescent homes, with 5212 beds, which have not been transferred under the Act still look to the Fund for support. In other fields the groundwork is already laid, covering aspects of the hospital services which will possibly always be best dealt with by an extragovernmental body. For example, through propaganda and the offer of training bursaries, the Fund is trying to raise the standard of hospital administration, catering, and domestic supervision; it is actively helping in nursing recruitment; and it is financing travel grants for the betterment of several departments of hospital life, including actual construction. Perhaps the activity most familiar to London's doctors is the Emergency Bed Service, now enlarged to serve all four metropolitan hospital regions. Last year the service made a survey of all mechanical respirators in the voluntary hospitals of Southern England; and the value of this precaution was proved in August when each of the many urgent calls was met. Less successful, through shortage of supplies, were the efforts to obtain streptomycin treatment for cases of tuberculosis meningitis and miliary tuberculosis. "The situation," says the annual report, "reached its worst in April, 1948, when 45 people were waiting for treatment with little or no prospect of obtaining it." Since then, however, it has improved.

INFECTION OF CHILDREN WITH TUBERCULOSIS

THE incidence of tuberculosis in children is low, but it has increased with the failure of the provisions for adult treatment. A report of the Joint Tuberculosis Council[1] has focused attention on sources of infection outside the home. Examples are quoted of the risk to infants and school-children from tuberculous persons whose duties bring them into close contact with the children. We report elsewhere a reply given by the Minister of Education to a Parliamentary question on tuberculous teachers. Education authorities have been reminded of the action to be taken when a teacher is found to be suffering from active tuberculosis, but no provision is made for the examination of teachers at regular intervals after entry into the teaching service, nor is sufficient importance attached to radiography as an essential aid to diagnosis. The examples quoted by the Joint Tuberculosis Council of infection and mortality among young inmates of children's homes and schools are appalling. Recently two further instances have occurred in a Greater London area. A young Irish girl, teaching in a private school, was found to have phthisis. She had reported her initial symptoms to a doctor in Eire, but the significance of her story was missed and she continued to teach, in England, for a further three months before she was referred to a chest clinic. In the second case a woman working in a day-nursery was found to have well-marked apical excavation. She was obviously capable of transmitting a virulent infection, and the amount and nature of morbidity among the children in the nursery is now being investigated. Such incidents can and must be prevented. For this purpose the following recommendations are made by the Joint Tuberculosis Council:

1. No person with pulmonary tuberculosis should be allowed to accept employment which will involve contact with organised groups of children until the disease has been certified as arrested.
2. All persons whose duties bring them into close contact with organised groups of children should at the time of their engagement undergo a medical examination, including an X-ray examination of the chest, and they should thereafter have an X-ray examination annually while so employed. The cost of these examinations should be borne by the employer.
3. If it is found that any employee is suffering from pulmonary tuberculosis, employment should cease at once and not be resumed until two consecutive medical certificates have been submitted, the first certifying that the disease is no longer active and the second that the improvement has been maintained for at least six months after the date of the first certificate.
4. When employment is resumed, similar certificates should be submitted at three-monthly intervals for a year and at six-monthly intervals for a further two years.

An unusually high incidence of pulmonary or non-pulmonary tuberculosis in any organised group of children, says the report, should lead at once to a full investigation of the staff employed. The fact that attendance at school is compulsory, and that many children are placed in homes or nurseries at the behest of some public authority, makes it a public responsibility to take the steps that are patently necessary to prevent tuberculous infection in these places. Dr. Wilfrid Sheldon and the children's committee of the Joint Tuberculosis Council will have their colleagues' full support in their efforts to abolish a grave and needless risk.

TREATMENT OF NASAL INFECTIONS

ONE of the most valuable advances in the field of otolaryngology during the past 15–20 years has been the elucidation of nasal physiology. The schneiderian membrane, or respiratory mucous membrane, is a pseudostratified ciliated epithelium. The mucus it secretes forms a continuous if tenuous sheet throughout the nasal cavities and accessory sinuses. The cilia are embedded in this sheet of mucus, and their whip-like movements act concertedly in moving the sheet bodily in specific directions. In each sinus the cilia shift the mucus to the ostium and into the nasal cavities, whence it is gradually moved into the nasopharynx. When sufficient mucus accumulates here it initiates a movement of deglutition and is swallowed. Solid or droplet particles in the respired air adhere to the mucus, which thus has a cleansing function, and, in addition, moistens and warms the air. Finally, at least one enzyme has been found in this nasal secretion which has an active antibacterial action, and there may be others with similar or complementary properties. Thus complex and important rôles are played by this unassuming hidden area of mucosa, and an appreciation of this physiology has led to a revision of ideas about nasal disease. For example, the patient who complains of a continual dripping of mucus ("catarrh") into the back of his throat can usually be reassured. But more important is the modern conception of infection and its treatment which has been based on the new knowledge of physiology. Nothing must be given or done which inhibits the normal functions of the mucous membrane—particularly ciliary activity—since these are the natural mechanism of resistance and drainage of the area. Besides the usual general measures of treatment of infections, mild vasoconstriction of the mucous membrane of the various sinus ostia is necessary to allow secretions to be evacuated in the normal way. The choice of drug and method of application have been extensively studied, notably by Dr. Arthur Proetz of St. Louis.

In a lecture at the Institute of Laryngology on June 28, Dr. Proetz demonstrated his suction-displacement method of treatment for acute and subacute nasal infections. It is possible to introduce fluid into an air-filled rigid-walled container through a small hole if the opening is covered with a layer of fluid and suction is applied. Air leaves the cavity and bubbles out through the overlying fluid, which enters and takes its place when the negative pressure is released. This hydrostatic principle is applied to the nasal sinuses by placing the head in such a position that the sinuses are lower than the nasal cavities. With the patient lying on his back with his head fully extended over the edge of the couch or table this can be achieved. Fluid is then introduced gradually through each nostril in turn until all the sinus ostia are submerged—various devices are used to ensure approximation of the soft palate to the posterior pharyngeal wall and thus prevent the fluid escaping into the pharynx. Each nostril in turn is closed by pinching, and while one is closed the tip of a sucker, connected to a source of intermittent suction of not more than 150 mm. Hg, is introduced into the other. Air can thus be evacuated to some extent from the most remote ethmoidal cell and replaced by fluid, provided the ostium of that cell is patent. The fluid used in treatment is a 0·25% solution of ephedrine in normal saline, and as this remains many hours in the sinus before being gradually expelled a continuous slight vasoconstrictive effect is exerted on the mucosa surrounding the ostium. This solution has been found, as a result of trial and error, to exert the optimum effect, since it has scarcely any action on the cilia, which function normally in its presence. The procedure is repeated in 48 hours and four or five treatments are needed in the average case. If the condition emains unchanged after eight or ten treatments, the nethod should be abandoned. Chronic infection is often elieved but rarely cured in this way, for irreversible hanges have usually occurred in the mucosa. As an id in diagnosis radio-opaque fluids may be introduced nto the sinuses and an appreciation formed of the hickness of the lining mucosa. The simplicity of the pproach was achieved only by clear thought and areful consideration of fundamental physiology, in the nderstanding of which Proetz and his associates have layed a pioneer part.

SURGICAL COMPLICATIONS OF TYPHOID FEVER

ABOUT the rarest surgical complication of typhoid ever is intestinal obstruction from band formation. Considering the nature of the pathological process, t is rather surprising that obstructive adhesions do not form more often. In the case reported by Dr. Kane n this issue there were two bands needing division, both of which compressed the small intestine. A sudden et of pain, a rise of pulse-rate with fall of tempera- e, and an absence of abdominal rigidity led to a gnosis of mesenteric thrombosis. An operation was ie within three hours of the onset of the crisis, but ugh the obstruction was relieved, the patient died the fifth postoperative day rather from the intensity the primary disease than directly as a result of the nplication.

n a monograph on surgical complications of typhoid er,[1] recently published in Germany, obstruction by nds is not even mentioned. But Detlefsen describes ier surgical happenings in detail, and his book is a ninder that such events should be borne in mind. not very prominently. The most common complica- n—perforation—occurs on average 1–5 times in every 0 cases. The perforation is not always in the expected ice—the lower 60 cm. of the ileum—for it is sometimes the appendix, cæcum, or any part of the colon including e sigmoid flexure, a fact to be remembered by the rgeon searching for the origin of a typhoid peritonitis. iere may be two perforations. Attacks of pain in the urse of typhoid are not uncommon. Diagnosis depends the suddenness and acuity of the attack, the collapse ith weak suddenly risen pulse-rate, the fall of tempera- ire, and the local tenderness and rigidity. A rectal amination reveals sensitiveness of the rectovesical ouch. A midline incision makes the search more easy. n rare cases the perforation is not of the bowel but f the gall-bladder. The symptoms may even arise from a ppurating mesenteric gland or exceptionally from the rganisms penetrating the peritoneal cavity without a erforation. After suturing a perforation it is advisable o drain the abdomen. The complication is very serious, or the death-rate even after operation is 92–93% and ithout operation all die.

The other complications needing surgical treatment nclude cholecystitis, appendicitis, and abscess of the pleen. In connexion with the problem of the typhoid arrier, Detlefsen insists that before removal of the ll-bladder is considered the patient should be treated r two years and it should be certain that the gall- adder is the offending organ. Foci in the appendix, nes, or kidneys should be carefully excluded. If this s been done and gall-stones are present, or if the wall the gall-bladder is obviously diseased, cholecystectomy n be counted on to give a permanent cure. How portant it is to deal with such carriers can be gathered om the statement that a single carrier was known to responsible for several hundred attacks of typhoid other people and ten deaths during his lifetime. one lesions due to typhoid call for early recognition and eatment. Their discharges are just as infective as those from the bowel—a fact apt to be forgotten. The spread of infection from them is very difficult to deal with in the surgical management of wounds and sinuses. It requires unremitting care and alertness combined with strict regard to the principles of aseptic wound technique.

CARCINOMA OF THE PANCREATIC HEAD

IN a lecture at the Royal College of Surgeons on July 8, Dr. R. B. Cattell discussed the lessons learnt from 56 pancreaticoduodenal excisions, for carcinoma of the pancreas or of the ampulla of Vater, performed at the Lahey Clinic. He reported no startling advance on the views which Whipple, Braunschweig, he, and others have already expressed in print,[1] but he dotted many i's and crossed some t's in his reflections on a series of cases which, for size, can have no rival in this country.

The diagnosis of operable pancreatic malignancy is largely clinical. The radiologist and pathologist can offer little help at the stage when these carcinomata can be resected. Jaundice is the common *presenting* symptom; it is also the *first* symptom of growths in the ampulla. In growths of the head of the pancreas proper, nausea and loss of weight usually precede the onset of jaundice, and, if the jaundice is long delayed, diagnosis may be extremely difficult. Deep boring pain in the upper lumbar region, relieved by change of posture, may suggest a pancreatic neoplasm, but laparotomy is often delayed till jaundice has appeared. This means that carcinomata of the body and tail of the pancreas (which are fortunately much less common than growths in the head) are seldom operated on until they are beyond excision. Most patients with pancreatic neoplasms are old, jaundiced, and in poor general health, and every possible method of improving their condition is needed if they are to survive radical excision. With this object in view Dr. Cattell recommends a two-stage operation for most patients, especially if they have been jaundiced for a long time. A loop of jejunum, with an entero-anastomosis across its base, is anastomosed to the gall-bladder as the first stage, and back-pressure on the liver is thus relieved. This measure does much more than all other forms of therapy put together for the patient's general condition. The jejunal loop, he claims, can easily be retracted to the right when, two or three weeks later, the second stage is done. The most important feature of the second stage is the anastomosis of Wirsung's duct to the jejunum. Total closure of the pancreatic stump by suture is not only a cause of fatalities by leakage of pancreatic juice into the peritoneum but is also a cause of failure, in those who survive, to gain weight after the operation. Another important point is the secure closure, by rows of sutures, of the proximal end of the common bile-duct, lest it leak bile into the peritoneum. The block excision of the pylorus, duodenum, head of pancreas (and the subsequent plumbing procedures to restore continuity to the gastro-intestinal, biliary, and pancreatic tracts) are an anatomical exercise which those who have done them know to be less childishly easy than Dr. Cattell's beautiful colour film would lead one to suppose.

The results of palliative cholecystjejunostomy at the Lahey Clinic for inoperable neoplasms are that 73% of the patients do not survive the operation by three months. Dr. Cattell has lately combined this operation with anastomosis of Wirsung's duct to the jejunum and has tied both pancreaticoduodenal arteries to decrease the vascular supply to the growth. It is not yet known whether this improves the depressing results of palliative surgery. By contrast, 43% of patients subjected to a radical resection live more than two years, 39% show signs of recurrence within two years, and 18% die in the postoperative period. Those who survive operation are restored to reasonable health. Sufficient time has not yet elapsed for a differentiation of prognosis of the

OCCUPATIONAL HEALTH

President : Dr. Donald Stewart

Human Relations in Industry

Approaching the subject "from the angle of a universalist rather than a specialist," Sir George Schuster emphasised the danger that the study of human relations may become merely a means to more production, rather than an end in itself. A threefold purpose in work is fundamental: there should be, first, excellence in production; second, a satisfactory foundation for a good life; and third, it should fit in with an established social culture. These three must be reconciled, and schemes which fail to do so will be both wrong and unsuccessful. To achieve satisfaction, workers must have confidence, and as this rests on coöperation there must be no conflict between work and social duty or social aspirations; practical difficulties exist that are often exaggerated. Solutions must be flexible and allow the individual scope. The medical officer's part consists in fitting the job to the man, and to do this he must be able to see the total picture. He should be one of the management team, and himself be available for high administrative office; he should take part in joint management committees and can contribute much to the appreciation of the individual as a human being. Industrial medical officers should form a group which can discuss current problems with the panel on human factors of the Cabinet committee on productivity, of which Sir George Schuster is chairman.

Dr. Elliot Jaques discussed the relation of morale to health and illness, and maintained that the success of medical practice in industry depends largely on the coöperation obtained by the medical officer. The behaviour of the leader determines the behaviour of the led, and the leader who inspires participation in the group produces the best results. The morale of the industrial medical officer is therefore essential in developing the morale and thus the health of the group.

In communicating ideas from one individual to another, the learner must participate in the formation of the idea. In applying this view to education in human relations, Dr. R. F. Tredgold contended that ideas must not be imposed, but there must be an atmosphere of friendliness and a gentle insistence on participation. People pay lip service to others' words; they act in accordance with others' behaviour. The pattern of relations in industry is based not on the religious and political views of the past twenty-five centuries but on the historical facts of the past one. Mr. J. F. Scott (Harvard) gave examples illustrating the need for sound material in the teaching. Words and behaviour should be regarded as symptoms of underlying emotions, and must not be taken only at their face value but as part of a total picture. If the feelings are straightened out the facts will take care of themselves.

Aviation Medicine as Applied to Civil Aviation

Air Marshal Sir Harold Whittingham included in his subject such widely diverse considerations as selection and care of all flying personnel and ground staff, with periodic tests of their health and efficiency, and the difficult decisions of retiring age, and the investigation of all aircraft accidents, however slight. He claimed that such accidents now average only 2 per hundred million passenger miles, 60% of them being in landing and taking off. It also covers the comfort and well-being of passengers, including seat design, safety belts, and oxygen appliances; the maintenance of safe water and food-supplies en route; the "disinsectation" of aircraft; and quarantine problems and the standardisation of vaccines and inoculation methods, which are best approached through the World Health Organisation.

Stratosphere Flying

This was defined by Wing-Commander W. P. Stewart as flying at 40,000 feet and over and (though conditions are not constant) at a temperature of 55°C and a pressure of 15 lb. to the square inch. At this height there are no cloud particles or moisture, the sun seems brighter—in fact, solar radiation is considerably greater—and the sky is dark purple. Stratosphere flying is a distinct possibility for passenger planes, particularly at night, and it has the advantages that air-sickness is non-existent and vibration much less. But before it can be achieved there must be great advances in aircraft design, to prevent failure of oxygen appliances which at these heights causes death from anoxia in 30–90 seconds, and to prevent vaporisation of the body fluids.

Fatigue in Flying

Sir Frederick Bartlett, F.R.S., divided fatigue into different types—e.g., of muscle only, of muscle plus brain, due to lack of sleep—and each kind has its own specific physiological and mental results. In flying the fatigue is of brain plus muscle and it includes all the demonstrable changes of activity due to the continued exercise of that activity under its normal range of conditions.

The air crew's activity consists in the continued interpretation of signals, received either from instruments or from other members of the crew, and their translation into planned action. This entails almost continuous readjustment and becomes largely automatic. Experiments by Carmichael and by Dearborn and in the "Cambridge cockpit" showed that in good conditions a healthy man can keep up this form of activity for six hours at least without ill effect. When deterioration does occur there are three diagnostic signs: (1) a bigger receptor change is needed to set off any effective response, so that ragged timing of operative movements results; (2) greater preoccupation with how the body works sets in and feelings of discomfort appear; and (3) the "anticipatory span" of action becomes restricted. Passenger fatigue still belongs to the realm of anecdote. Passengers probably suffer more from boredom than from actual fatigue, but the objective effects are much the same and there is room for much more investigation in this field.

SECTION OF PHARMACOLOGY

President: Prof. E. B. Verney, F.R.S.

Anti-histamine Substances

It is now nearly forty years since the dramatic pharmacological actions of histamine were first recorded. Recognition of the close similarity of its effects to the manifestations of anaphylactic shock was followed by observations of its action on the tone and permeability of capillaries, and its presence in normal cells, and of a histamine-like substance released in the skin in response to injury. Histamine has also been detected in the blood-stream during anaphylaxis. This was recalled by Sir Henry Dale, F.R.S., who went on to say that when histamine is released during allergic reactions it may act either on the cells releasing it or on others at a variable distance. Is there evidence of a difference between the effects of anti-histamine drugs on the reactions to "intrinsic" and "extrinsic" histamine? It is reasonable to expect that intrinsic histamine would produce its pharmacological effects with little, if any, ampullary growths and those of the head of the pancreas, but there can be little doubt that the ampullary neoplasms, because they attract early attention by causing jaundice, will be found to do better than growths in the pancreas proper.

GRIEF IN INFANCY

YOUNG delinquents, particularly those described as "affectionless," so often have a history of separation from the mother during their early years that a study has long been needed of infants who suffer this particular deprivation. Dr. René A. Spitz, who has been working on this subject in America, described his findings to the Royal Medico-Psychological Association on July 9, and showed a film. He has been able to watch large numbers of infants over long periods, in nurseries, private homes, foster homes, a foundling institution, and a maternity home, and in an Indian village. Children in a nursery where they normally are reared by their own mothers under supervision were particularly suitable for his purpose, since their behaviour could be compared with that of plenty of controls. He has seen nineteen children between the ages of 6 and 12 months whose mothers have been obliged for some reason to leave them for a time. The child learns nothing without the help of the mother during the first year of life: hearing, touch, taste, walking, orientation, thinking, will, and speech are all learned through her, and her ego, he said, is complementary to the immature ego of the child. The loss of the mother cannot therefore be compared with the bereavement of a grown-up person: the child loses its actual chance of developing. Dr. Spitz has analysed children's progress in perceptive, bodily, social, learning, manipulative, and intellectual development during the first year of life, and is able to calculate a developmental quotient (D.Q.). The assessment is made by analysis of films made of the children at play, a method which owes nothing to personal relations between child and observer.

He finds that the effects of separation from the mother in children aged 6–12 months fall into three stages. After the first month of separation, the child becomes tearful; his progress falls off in every way, though the social factor is increased relatively to the other factors since his desire for social contacts is increased. After the second month this picture changes; the child, who before the mother's departure was friendly and sociable, now takes to screaming at strangers and cannot be soothed by ordinary methods. Screaming bouts may last as long as three hours. He begins to lose weight, and the D.Q. is arrested. In the third month he gives up all attempts to crawl or walk, and adopts an attitude which Dr. Spitz describes as pathognomonic: he lies on his face and refuses all social contact. He loses more weight, sleeps badly, and becomes accident-prone and subject to intercurrent ailments. In the fourth month his face acquires a frozen-dazed look, his screaming and tearfulness are replaced by a whining moan, and his D.Q. sinks even lower. This stage, if unchecked by the return of the mother, may go on to marasmus. Dr. Spitz suspects that the turning-point is somewhere between the third and the fifth month: after that, separation from the mother leaves irreversible changes, whereas her return before this point produces cure within a period of from 12 hours to 14 days. The D.Q. leaps up again, and though it may go back a little later, it never regresses to the point it reaches during separation.

His film *Grief, a Peril of Childhood* shows children who illustrate all the stages he described. The change from a smiling confident baby to a forlorn and anxious one is very striking, and the attempt the child makes, in the first month of separation, to cling to any friendly person while continuing to weep disconsolately is a vivid expression of inner despair.

If the mother cannot return, or if she has died, the child must be given a substitute, and helped to accept her; and he will also need to be encouraged to crawl and walk again. It is interesting that these symptoms of deprivation are only seen when the relationship of mother and child is a good one: where the relationship is poor the child accepts his mother's departure with equanimity.

DIAGNOSIS OF MITRAL INCOMPETENCE

So much has been written about the insignificance of apical systolic murmurs that the practitioner may well have decided that the safest line is to ignore them. In fact—and this applies to most of the signs and symptoms of medicine—mistakes are likely to be made only when this murmur is considered as an isolated finding. It must be borne in mind (*a*) that an apical systolic murmur should never be the basis of a diagnosis or prognosis without reference to the other findings and to the patient's history, and (*b*) that mitral incompetence is not a rarity but the almost inevitable precursor of mitral stenosis.

These points are brought out in an American analysis[1] of 315 rheumatic children discharged over a period of fifteen years from a sanatorium for children with rheumatic heart disease. The children were divided into two groups according to their cardiac status on discharge: group I consisted of 171 cases with soft, poorly transmitted apical systolic murmurs and classified as having potential or possible rheumatic heart disease; group II consisted of 144 cases diagnosed as mitral insufficiency because of a loud blowing systolic murmur maximal at the apex and well transmitted to the axilla, even though there was no evidence of cardiac enlargement. The follow-up ranged from five to fifteen years, with an average of eight years. In group I, 22 patients (13%) developed definite cardiac lesions and there were no deaths; 16 had mitral stenosis, with or without mitral incompetence and aortic incompetence. In group II, on the other hand, 69 patients (48%) developed definite cardiac lesions and 20 died; 53 had mitral stenosis, with or without mitral incompetence and aortic incompetence. Of the children in group I, 53 (31%) had had multiple attacks of rheumatic fever before coming under observation, while 12 (7%) had recurrent attacks during the follow-up period. The comparable figures for group II were 92 (63%) and 28 (19%).

The conclusion drawn from these findings was that "the diagnosis of mitral insufficiency, based on a loud blowing apical systolic murmur, is justified in children, even in the absence of demonstrable cardiac enlargement." This is important, especially in view of the difficulty in detecting minor degrees of enlargement, even on fluoroscopy. It may be added that if such a loud apical systolic murmur is accompanied by evidence of cardiac enlargement the prognosis is worse. It is noteworthy that 13% of group I developed a definite organic cardiac lesion though their only abnormal sign when they were first seen was a "soft, poorly transmitted apical systolic murmur." The fact that made this finding significant is that they had had one or more attacks of rheumatic fever.

Lord WEBB-JOHNSON has been re-elected presid of the Royal College of Surgeons.

---

[1] Kuttner, A. G., Markovitz, M. *Amer. Heart J.* 1948, 35, 711

THE Ministry of Health announces that about 21,3 general practitioners in Great Britain had applied by July to take part in the National Health Service. Doctors have accepted over 36,700,000 people, of whom 22,200,000 were previously on National Health Insurance lists. The Minister of Health has stated that if substantially more than 17,9 practitioners agreed, by July 5, to enter the service, the sum of £66 million offered in compensation for the loss of the right to sell practices would be proportionately increased.

nissing " sternebra corresponding to the sixth costal rtilage and rib as a small bilateral ossification centre, on to disappear by fusion with the fourth sternebra.

The interrelation of the prosimians was discussed by of. W. C. **Osman Hill**. The specialisations of the adagascar " lemuroidea " render them unlikely ancesrs of the higher primates. The oriental and African lorisoids," though showing specialisations, may conivably have arisen from a more generalised lorisoid, ffering little perhaps from an equally generalised rsioid. Some of the higher primates and later tarsioids ay have arisen from such a stock. The lack of detailed natomical information prevents a full assessment of e intergroup relationships. Professor Hill dealt fully ith the position of tarsius and some of its eocene fossil llies.

Illustrating his talk on the nasal fossa and paranasal nuses of the primates with detailed drawings, Prof. J. E. **Cave** characterised the primate type of nasal ssa as a short, high-pitched, forwardly situated cavity ith a reduced interorbital region and without a lamina ransversa or recognisable ectoturbinals. The immediate nechanical factors responsible for its form are cerebral xpansion and large eyes and orbits. He illustrated the xpansion of the paranasal sinuses, irrespective of their ite of origin, to almost every bone in the skull, together with the frequent extension into them of the turbinals. He emphasised the complexity of the region and the lifficulties attendant on its study.

From his observations on monkeys bred in the anatomy lepartment at Birmingham, Dr. F. M. P. **Eckstein** gave a detailed account of the dentition in the rhesus monkey, discussed the time and sequence of eruption of both deciduous and permanent teeth, and compared he teeth of rhesus monkey and man. He assessed he value of the information gained from these studies n estimating the age of specimens.

Dr. D. V. **Davies** called for more data in relation to he primate cardiovascular system. The complexities of the peripheral vascular system in the primates are n many places incapable of interpretation owing to ack of information. He discussed the effect of freeing he limb from the tissues of the trunk and the effect of lifferentiation and development of the muscle masses on the branches of the subclavian and axillary vessels and of the external iliac and femoral arteries. He also discussed factors contributing to the pattern and development of the arterial arches of both hand and foot and deplored the lack of knowledge regarding the branches of the internal and external carotid arteries.

The whole theme of this session was the need for further dissection of the primates. Thorough understanding of the position and interrelation of the various species awaits a revival of this time-honoured but much neglected approach to primate anatomy.

PHYSIOLOGY INCLUDING BIOCHEMISTRY

President : Prof. A. C. **Chibnall**, F.R.S.

With its meetings devoted to the medical significance of proteins and the physiological basis of neuromuscular lisorders, the title of this section might well have been Biochemistry including Physiology.

Recent Work on Proteins

Professor **Chibnall**, cautiously reviewing recent work on protein structure, with special reference to amino-acid nalysis, emphasised the difficulties encountered in elucidating the structure even of such proteins as insulin, with a molecular weight of 12,000 ; and he held out no mmediate hope of similar advances in the case of larger rotein molecules. Mr. J. A. V. **Butler**, D.SC., emphaised the danger of over-simplification in interpreting electrophoretic data : he viewed the prospect of " consulting-room electrophoresis " with some alarm.

Dr. **Leonard Colebrook**, F.R.S., and Mr. **Dallas Ross** described the treatment of burns at the special Medical Research Council unit at Birmingham. The volumes of plasma transfused are very large—up to 22 litres in one case—and are controlled principally by hæmatocrit readings. The results have been so successful, particularly in the younger age-groups, that many patients have recovered from burns of more than half their skin. These patients give rise to considerable surgical problems, but the grafting process is greatly helped by the new thrombin-fibrinogen glue. A simple apparatus for measuring the adhesive power of this glue excited general admiration.

Prof. E. C. **Dodds**, F.R.S., described recent work on the chemistry of the anterior-pituitary hormones and spoke of their great therapeutic possibilities. Here indeed are the hormonal " master keys." With the possible exception of the growth hormone, none has yet been obtained in a crystalline state. They are unstable substances, and commercial preparations are sometimes of doubtful potency.

Prof. G. W. **Pickering**, who reviewed the renin situation, could not claim that any type of chronic hypertension is produced by the renin mechanism. Thus even the chronically hypertensive Goldblatt animal has no demonstrable excess of renin. There must therefore be some other mechanism responsible for chronic hypertension.

Prof. N. F. **Maclagan** dealt with some nine flocculation tests which depend mainly on serum γ-globulin. He expressed a preference for the thymol and colloidal-gold tests and thought that they have considerable diagnostic importance and many unexplored applications in protein chemistry and in immunology.

Neuromuscular Transmission

The second session was opened by Sir **Henry Dale**, O.M., with a masterly review of the evidence for the chemical transmission of nerve impulses at the myoneural junction, illustrated by special reference to the action of curarine and botulinus toxin. If any doubters had been present they would have been convinced. This work still has a powerful appeal to the scientific emotions and produces a feeling of intense intellectual satisfaction. Sir Henry pointed out that the actual clinical applications of the theory have proved somewhat disappointing, but the recent work on the organic phosphates in myasthenia gravis may be considered a logical development of it. As a corollary there is evidence that in certain synapses neither acetylcholine nor adrenaline are acting, and the existence of at least one further chemical transmitter was postulated.

Prof. F. R. **Miller**, F.R.S. (University of Western Ontario), described experiments on the local application of acetylcholine to the central nervous system which he interpreted as evidence of normal function of acetylcholine in this region. Further evidence pointing in the same direction is the distribution of the enzyme cholineacetylase in the C.N.S., reviewed by Dr. W. S. **Feldberg**, F.R.S. The presence of this enzyme in high concentration provides suggestive, though not conclusive, evidence for transmission by the acetylcholine mechanism. Mr. **Bernard Katz**, D.SC., differentiated unicellular transmission, which is electrical in character, from synaptic transmission, which is chemical.

Dr. **Andrew Wilson** described the treatment of myasthenia gravis with di-iso-propyl-fluorphosphonate (D.F.P.), which is moderately successful but gives rise to certain side-effects such as nightmares. Changes in the true and pseudo-cholinesterase in the blood have little correlation with symptomatic relief. Dr. C. A. **Keele** has used mainly tetra-ethyl-pyro-phosphate (T.E.P.P.) for myasthenia. Its action is more prolonged than that of ' Prostigmin,' but cumulative effects occasionally produce diarrhœa and/or nightmares.

interference from anti-histamine drugs; and this may in fact be the case with the bronchial musculature. On the other hand, there is ample evidence for the potent effects of these drugs in diminishing or abolishing urticarial phenomena in the skin where histamine is acting on vascular structures probably some distance from the area in the skin where it is released. Several questions remain unanswered. How is histamine liberated and in what form does it normally circulate in the blood-stream? Does it play a rôle in normal tissue activity, and if so what is its functional significance? Do these considerations affect the practical use of anti-histamine drugs?

The story of modern anti-histamine drugs was taken up by Prof. J. H. **Gaddum**, F.R.S. The preparation of Bovet and Staub—929F—was originally studied for its anti-adrenaline action and only later found to have anti-histamine properties. Bovet introduced 'Neoantergan' in 1944, and this is at present the most potent and specific anti-histamine drug that is to be had. The similarity in the structure of neoantergan and histamine is additional evidence about the probable mode of action of anti-histamine drugs. In a brief survey of the other properties of this group he pointed out the possible relation between local anæsthetic effects and the relief of itching: in human beings somnolence often follows their administration, whereas in animals the central nervous system is stimulated.

Touching on clinical applications, Dr. R. B. **Hunter** stressed the importance of comparative anti-histamine studies in human beings as a method of assessing the potence of new preparations. Their major clinical use is in the treatment of urticaria. They have little effect on the skin manifestation of drug reactions unless these are urticarial. Eminently successful in the treatment of hay-fever, they also greatly benefit more than half the cases of perennial rhinitis, and they have proved their value in the treatment of sensitivity to liver extracts. Their main sphere of usefulness is in the treatment of those disorders which are characterised by superficial vascular phenomena. It is doubtful, said Dr. Hunter, whether any benefit can be attributed to them in the relief of asthma. Dr. H. G. J. **Herxheimer**, on the other hand, considered that they will benefit some cases of asthma when all other forms of treatment have failed.

Agents Affecting the Pars Nervosa

Professor **Verney** pointed out that the diuresis resulting from ingestion of water can be inhibited by emotional stress, exercise, the intravenous injection of posterior-pituitary extract, or the intra-carotid injection of hypertonic saline. The inhibition is independent of the nerve-supply to the kidney; it is unaccompanied by any change in the renal blood-flow; and it is not caused by the endogenous release of adrenaline. The response to sodium chloride is osmotically determined, and the term osmo-receptors has been introduced to describe the autonomic receptive elements which are located somewhere in the vascular bed of the internal carotid artery and which are functionally linked to the neuro-hypophysis. The same effect can be demonstrated when the increased osmotic pressure of the blood is within the physiological range.

Dr. L. M. **Pickford** said that nerve impulses arising in the higher centres also affect the rate of urine flow by their effects on the neurones which innervate the posterior lobe of the pituitary and thereby influence the amount of antidiuretic hormone liberated. Acetylcholine given intravenously or applied directly to the supra-optic neurones in the dog has an antidiuretic action. The inhibition occurs after denervation of the kidney, but does not occur when the posterior lobe of the pituitary has been removed. Additional evidence was presented to support the theory that transmission of nerve impulses in the supra-optic nuclei is by acetylcholine.

In this connexion Dr. W. S. **Feldberg** said that he had recently found that the posterior pituitary had no power to synthesise acetylcholine, but that the supra-optic nuclei gave high values.

The administration of nicotine intravenously in animals and in man results in an inhibition of water diuresis—an effect which is not produced in hypophysectomised animals. Prof. J. H. **Burn**, F.R.S., pointed out that in man the smoking of cigarettes can produce a similar effect which, in the susceptible individual, may last several hours. In animal preparations the administration of nicotine results in reduction of coronary blood-flow. If this is produced in man by the smoking of cigarettes, it is of considerable importance particularly in cases of coronary insufficiency.

Dr. W. J. **O'Connor** reported his studies on the response of the dog's kidney to the intravenous administration of hypertonic salt solutions. He presented evidence that the antidiuretic hormone controls the volume of fluid excreted by the kidney but is without influence on the total quantity of salt excreted.

ANATOMY AND ANTHROPOLOGY

President: Prof. H. A. **Harris**

Present Position of Primate Anatomy

The stimulating opening address, by Prof. F. Wood **Jones**, F.R.S., left the young anatomist in no doubt about his obligations in the field of primate anatomy and the need for a return to the scalpel and forceps. Professor Wood Jones attributed much of the misunderstanding regarding man's progenitors to the unqualified acceptance of the views of Darwin and Thomas Henry Huxley, neither of whom had the necessary first-hand knowledge of primate anatomy to support his pronouncements. Their postulates, it seems, were often ill-based and frequently ignored much of the available information which has since been proved reliable. Had Darwin been fully conversant with the works of Vrolik he would have known in detail the incidence of the entepicondylar foramen in the primates, of which, in man, he asserted, "there is generally a trace of this passage and it is sometimes fairly well developed." Likewise, Huxley's comparison of the development of dog and man was ill-founded and misleading, yet Darwin accepted this comparison without question. Professor Wood Jones pointed out that both Darwin and Huxley so influenced public opinion concerning the relation of man to the apes that their pronouncements led to much false satisfaction about man's phylogeny and produced a lull in original investigation which still lurks in our midst. Not until dissection of the primates reasserts itself as a method of investigation will the complexities of the problem be fully realised, not until the anatomist again takes up his scalpel and forceps shall we have the clarity of thought necessary to unravel this problem and to rid ourselves of the illogical arguments which still prevail.

Next Professor **Harris** discussed the value of radiography in the study of primate anatomy, particularly in view of the shortage of material and the lack of opportunity for dissection. The radiographic study of dolichocephaly, brachycephaly, and prognathism, together with their development, is well illustrated in the apes. He discussed tooth development and eruption and stressed the importance of the condyloid cartilage in the growth of the lower jaw. Most interesting perhaps were the radiographs of the developing pisiform bone in apes and monkeys. Possession of an epiphysis raises it to the level of a true carpal element. Professor Harris showed radiographically that the sternal angle in the gibbon is at the level of the third costal cartilage and not infrequently at the fourth, while he identified the ected cases respond satisfactorily and it appears that lio-iodine will have a useful place in the treatment cases of hyperthyroidism which recur after surgery. ere is probably little risk of late carcinogenesis, but ation is obviously necessary. Only a small proportion all cancers of the thyroid retain the function of iodine ncentration sufficiently to deliver therapeutically useful ses of radiation with radio-iodine, although there are tremely rare cases where functional secretion is a iking feature of both the primary and metastases and ere dramatic results can be obtained by radio-iodine erapy.

In general, it must be concluded that therapeutic ials of radioactive isotopes administered internally ould be limited to cancer and allied diseases; including lycythæmia vera. Professor Mitchell expressed the inion that it would be wise to avoid the therapeutic e of radioactive isotopes in any conditions in children.

This section held a joint meeting with the section of ild health to discuss Malignant Disease in Childhood ee below).

CHILD HEALTH

President: Sir **Leonard Parsons**, F.R.S.

The most notable events in this section were the iscussions on Neonatal Morbidity and Mortality and on alignant Disease in Infancy and Childhood.

eonatal Morbidity and Mortality

This discussion was opened by Dr. **Agnes R. acgregor** whose experience of neonatal pathology is nsurpassed in this country. She spoke of the great dvances which have followed routine necropsy of stillorn and newborn infants, and insisted that there is no ranch of medicine in which close collaboration between linician and pathologist is more rewarding. In a teachg maternity hospital she has found that 71% of newborn nfants coming to necropsy are prematurely born. sphyxia, intracranial hæmorrhage, and infections were otably commoner in premature than mature infants; nd the same was true, to a lesser extent, of congenital alformations. The escapist term "atelectasis" as a ause of death was rightly condemned, for it is never rimary.

Prof. **L. S. Penrose** discussed the ætiology of conenital malformations. He believes it is often impossible o differentiate between congenital malformations caused y inherited mutant genes, new mutations, and aberrant ntra-uterine development. He recalled the need to study he pedigree when investigating the origin of congenital haracters and anomalies. Most congenital abnormalities re inherited—particularly minor ones, since children ith major defects often perish. There is a 5% chance f an anencephalic fœtus being followed by a sibling with pina bifida, and another 5% chance of siblings having ther malformations. The incidence of congenital malormations is higher in offspring born at the extremes of he reproductive period and particularly towards the pper extreme; 24 years is probably the safest hild-bearing age from both this and the obstetric iewpoint.

A pertinent account of modern trends in the nutrition f premature infants was given by Dr. **Winifred Young**, ho recalled that premature infants retain more protein, alcium, and phosphorus per unit of weight than do ature infants. This fact deserves wider recognition, s also does her assertion that even small premature nfants are able to digest their full requirements, which re small during the first few days owing to a low metaolic-rate, and thereafter exceed those of mature infants. ppreciation of these facts has produced more rapid eight gain and better health in premature infants than ormerly, with closer approximation to normal intraterine nutrition in the later weeks of pregnancy.

The contribution of obstetric factors to neonatal morbidity and mortality was reviewed by Prof. **N. B. Capon**. He pointed out that the premature infant's brain is particularly liable to be traumatised at birth, owing to the softness of the immature protective bones and membranes. Intracranial hæmorrhage is a less important cause of signs of cerebral irritation than excessive compression, venous congestion, and œdema. Anoxia is a major danger, particularly with antepartum hæmorrhage and trauma to the fœtal head. Professor Capon commended the modern obstetric practices of avoiding unduly long labour and of more often performing elective cæsarean section; for these trends have improved the prognosis in many cases of complicated birth. He spoke of the need for caution in the use of analgesics and anæsthetics, which are a major cause of apnœa after birth, and of consequent morbidity and mortality in the newborn.

Dr. **J. L. Henderson** emphasised the greater risk of infants contracting infections in crowded institutions than in the home. He deplored the prevailing trend towards confinement in maternity hospitals and nursing-homes, since few institutions have been built in accordance with modern opinion. Mammals instinctively leave the herd and seek isolation to give birth to their young, and tend them in the early days: human mothers are no exception—a fact often ignored in this materialistic age. In the first week of life the incidence of infections is low, but thereafter it is high, causing more morbidity and mortality than all other disorders. The tissues of the newborn infant react poorly to infection, for there is a lack of specific active immunity, and local tissue response is poor. Inherited passive immunity is a partial safeguard; but active immunity develops unduly slowly in the first six months. The common neonatal infections—staphylococcal dermatitis, conjunctivitis, and oral thrush—are usually contracted after birth. Staphylococcal infection, which is endemic in maternity hospitals, is much the commonest cause of neonatal infection. The frequency of staphylococcal infections in infants, mothers, and nurses can be correlated. In addition to the various forms of dermatitis, such as paronychia and bullous impetigo, *Staphylococcus aureus* causes most cases of conjunctivitis. Oral penicillin therapy is reliable in the first month of life; it may be given in doses of two 10,000-unit tablets, crushed and dissolved in a little milk at each feed. Thrush should never be regarded as a benign disease since it may occasionally invade the œsophagus when it may cause death. Epidemic gastroenteritis, the most dreaded neonatal infection, is probably caused by a variety of organisms. The need for constant vigilance and immediate isolation of cases of suspected infection in institutions is paramount; and dispersal of infants with their mothers in single rooms or very small units is desirable.

Malignant Disease

This discussion was introduced by Prof. **Wilfrid Gaisford** who summarised contemporary knowledge of the clinical features and pathology. He showed that the problem is by no means negligible, since 4429 children under 14 years had malignant disease in Britain in a recent 5-year period. He insisted that with recent therapeutic advances the old pessimistic attitude is no longer warranted. Tumours are commoner in the first 5 years than in later childhood. The three principal groups of malignant tumour in children are intracranial tumours, leukæmia, and renal tumours. The most common intracranial tumours are medulloblastomas and astrocytomas; both are curable—the former by radiotherapy and the latter by neurosurgery. Unfortunately, it is usually impossible to differentiate these tumours without surgical exploration. Malignancy should be suspected when persistent swellings and persistent adenopathy are found. The curability, in many

RADIOLOGY

President: Dr. S. COCHRANE SHANKS

Radioactive Isotopes

In opening a discussion by the radiotherapeutic part of this section, Prof. O. R. FRISCH, F.R.S., of the Cavendish Laboratory, summarised the behaviour and properties of radioactive isotopes. All elements have radioactive isotopes—i.e., species with identical chemical properties but different atomic weight, whose nuclei are unstable. Only radioactive bodies with a half-life at least comparable with the age of the universe, and their descendants, which are often shorter-lived, are found in nature. All other radioactive isotopes, and in fact most of those in use, must be produced artificially, by bombarding some stable element either with fast-moving ions, from a cyclotron or similar apparatus, or with neutrons from a chain-reacting fission pile. Many isotopes can be produced in fairly concentrated form by chemical separation methods. In a pile, capture of slow neutrons will convert a little of the ordinary stable phosphorus isotope, P^{31}, into radioactive P^{32}; but this cannot be easily separated, and the radioactive isotope is consequently obtained only in a very dilute form. However, some of the fast neutrons from the pile can be used to convert stable sulphur 32 into radioactive P^{32}. This can be extracted by ordinary chemical means and obtained in a concentrated form, though only in small amounts. The possible replacement of radium by cobalt 60, an artificial gamma-ray emitter, was mentioned. The method of depositing a suitable isotope, or special compound of one, at the appropriate place in the organism by the utilisation of metabolic properties is probably capable of considerable development. Geiger counters are mostly used to measure the weak radioactivities encountered in medical and biological work, especially in the use of radioactive tracers. An entirely different counter is now being developed, based on recording the small flashes of light which fast electrons produce in passing through naphthalene and some other chemicals. This method may be useful for counting gamma rays. Recent developments of autoradiography include the use of emulsions poured on to the histological preparation and subsequently developed. A more elaborate technique makes use of a kind of electron microscope in forming an enlarged image of the specimen by focusing the electrons emitted by the radioactive tracer deposited in the section. For this method, the tracer must show the kind of radioactivity in which electrons of well-defined energy are emitted.

In a paper on the Biochemical Applications of Radioactive Isotopes as Tracers, Dr. A. S. MCFARLANE said that experiments with P^{32} to study the metabolism of bone and muscle illustrate the general pattern of a vast amount of biochemical work which is going on with tracers. It has become evident that within the cell there exist numerous chains of metabolic reactions leading from the simplest diffusible metabolites to highly complicated molecules and macromolecules. These chains cross at different levels and establish, at the intersections, metabolic pools in which the tracer element escapes in some measure from one pathway into others. In each kind of cell there are some favoured chemical reactions determined by its enzyme heritage. It is an important part of modern biochemistry to discover what the favourite reactions are. The precursor type of radioactive tracer experiment goes extremely well with amino-acids, sugars, keto-acids, and hydroxy-acids, and indeed with the general run of intermediary metabolites. With the highly important organic phosphorus compounds a difficulty arises—that no labelled substance has yet been found from which the phosphate radical is not detached at once in the tissues. In this important field attention should be focused more on the carbon skeletons to which the labile phosphate groups are attached. Dr. McFarlane mentioned also the use of radioactive tracers as non-specific indicators—e.g., the use of sodium 24 to determine the volume of the extracellular space and to measure blood-flow.

In general, it can be said that a new biochemistry is being discovered by the use of isotopic tracer methods. In all this work the Americans have achieved great progress. However, ample supplies of isotopes for tracer purposes are now available in this country, mostly from American sources but also from Canada, and home production is rising steeply. These isotopes are already being used in about sixty medical research projects covering a wide range of investigations.

Radiotherapeutic Aspects of Radioactive Isotopes were discussed by Prof. J. S. MITCHELL, who emphasised that the immediate field of application of radioactive isotopes as therapeutic agents and radioactive sources is relatively limited. From the long-term point of view the treatment of cancer and allied diseases is most likely to be advanced by the encouragement of tracer investigations using both radioactive and non-radioactive isotopes. So far our experience of radioactive isotopes in this country has been limited to tracer amounts. It is now evident, mainly from American work, that radio-phosphorus, P^{32}, used as inorganic phosphate, and to a much smaller extent the radio-iodines, especially I^{131}, can justifiably be employed as therapeutic agents for internal medication in some cases. The suitability of radiocobalt, Co^{60}, as a source of gamma radiation for radiotherapy has been confirmed, and there is a limited scope for artificial radioactive isotopes in beta-ray applicators. Radiophosphorus and the radio-iodines are the only selectively concentrated isotopes, and radiosodium, Na^{24}, is the only uniformly distributed isotope whose use in soluble inorganic form for internal administration has reached the practical therapeutic stage. Professor Mitchell mentioned investigations with the weakly radioactive radiocalcium, Ca^{45}, the radio-arsenics in leukæmia, and the interesting element astatine 85^{211}, which is concentrated in the thyroid. With radio-strontium, Sr^{89}, there is a risk of carcinogenesis. The use of insoluble radioactive colloids, including $CrP^{32}O_4$, $Mn^{52}O_2$, and Au^{198}, by intravenous injection in the treatment of reticulo-endothelial diseases and for the "injection implant" has been reported. It seems doubtful whether the therapeutic use of inorganic radioactive isotopes, even P^{32}, will stand the test of time, and the development of selectively concentrated organic compounds carrying radioactive isotopes is a much more promising line of approach.

The physical properties, dosimetry, and practical radiotherapeutic applications of P^{32}, I^{131}, and Na^{24} were next discussed. Radiophosphorus has been used in the treatment of patients since 1936. The only disease in which it has been found to give better results than X-ray therapy is polycythæmia vera, in which it is now generally believed to be the treatment of choice. The possible risks of induction of acute leukæmia in a small proportion of cases and production of deleterious effects on the reproductive organs were mentioned. In chronic myeloid and chronic lymphatic leukæmia the results and limitations of radiophosphorus therapy are similar to those of X radiation, and supplementary X-ray therapy may be needed. In most cases of lympho-sarcoma treatment with radiophosphorus is probably less beneficial than with X rays. The response of Hodgkin's disease is unsatisfactory and P^{32} is useless in acute leukæmias. In cancer generally radiophosphorus administered as inorganic phosphate is of no therapeutic value. Radiosodium is probably less effective as a therapeutic agent than is radiophosphorus.

Most of the clinical trials of the radio-iodines in the U.S.A. have been carried out in hyperthyroidism

Cross doubts whether it will ever be possible to rantee comfort. Perhaps there will always be a ority in whom conjunctival irritation or œdema of corneal epithelium will render contact lenses lerable.

Ir. J. G. **Drummond Currie**'s thoughtful concern with visual problems of industry is known to those who rd his paper[2] at the 1947 Oxford Ophthalmological igress. In his present contribution, Optical Aids to the ier Man's Job, illustrated with his own drawings, Currie pointed out that magnification is the main iciple in most of the optical aids contrived for ustrial work, but many other devices, such as the ing mirror, could be further exploited.

Speaking of the Heredity of Eye Disease, Mr. B. P. H. **attie** recalled that many congenital defects formerly ught to be inherited are now known to be transmissible the fœtus by the maternal blood. Therefore it is not ays possible to say whether a given lesion is hereditary environmental. He referred to the various modes of ieritance and noted that retinitis pigmentosa may handed down in five different ways.

In his paper on Nutritional Eye Diseases, Mr. **Hugh ran** dealt chiefly with prisoners in the Far East dicted with nutritional retinopathy. He suggested that urred vision is the most important initial symptom, id that ocular changes seldom arise until many months ter nutrition has been curtailed. Central and para- ntral scotomata are the most important field defects, id a characteristic feature is fragmentation of the otomata during recovery. Restoration of sight is the ile in cases where adequate nutrition can be supplied on after the onset of ocular symptoms. Otherwise sting impairment of vision is likely. Mr. Ryan empha- sed the variability of conditions in different camps, id the corresponding diversity in fundus lesions. The iief ophthalmoscopic signs are obliteration of the foveal flex and macular mottling. Hyperæmia and slight velling of the disc often occur, but Mr. Ryan, aware of ow widely the colour of the disc may vary within normal nits, advised against sweeping deductions when people ieak of "slight temporal pallor." Other features occa- onally noted are "broken-stick" (acute bends) and tenuation of the retinal arteries, and turgidity of the orresponding veins. Mr. Ryan contended that the mptoms, field defects, and ophthalmoscopic signs in iese cases preclude the label of "retrobulbar neuritis." he condition should be regarded as a form of retinopathy rought about by capillary dysergia (Stannus). The iacula suffers most because of its peculiar pattern of lood-vessels and high oxygen requirement.

NEUROLOGY AND PSYCHIATRY

President : Prof. E. D. **Adrian**, O.M.

pilepsy of Late Onset

Sir **Charles Symonds** analysed a series of 130 cases ferred to him because of epileptiform convulsions ppearing after the age of thirty. In 56 of them investi- ition supplied no reasonable explanation of the attacks, it 15 of these later proved to have a cerebral tumour. i patients with focal epilepsy, air studies, if negative, ould be repeated at intervals. Dr. **Denis Williams** scribed how the abnormal electro-encephalographic aves which occur during recovery from head injury ay gradually give way to secondary indirect changes ggestive of clinical epilepsy. Mr. D. W. C. **Northfield** id Dr. **James Bull** spoke of the help that may be spected, in the early diagnosis of brain tumour, from diography of the skull, air studies, and arteriography.

mile Deterioration

From his survey of 477 old people in Wolverhampton r. J. H. **Sheldon** gave an account of the various symptoms which may cause incapacity in the elderly. Common complaints include difficulty in getting about in the dark, fears of traffic, weakness, vertigo, and falls. The inner ear seems to be unusually sensitive to involutional changes, more especially in men. Dr. **Macdonald Critchley** discussed the problem of when involutional changes actually start, and the question whether old age is a normal physiological activity, a pathological process, or both. Though wisdom does not necessarily come with age, compulsory retirement at 60 or 65 deprives the community of an important asset—the accumulated experience and intelligence of people in their seventh and eighth decades. The span of healthy life may yet be expanded; and among factors that reduce it he included tobacco, which, he said, seems to shorten the expectation of life in direct proportion to the amount smoked.

Mrs. A. V. **Hill**, speaking as one of the laity with a close knowledge of old folks' homes, divided the aged into (1) cases of senile dementia, (2) persons of weak intellect who have grown old, (3) the "aged crank," and (4) patients with simple senility. Trained nurses do not make the ideal attendants, and the discipline of the sickroom is unnecessarily irksome to the aged. Dr. **Trevor Howell** dealt with some of the physical and mental concomitants of ageing, while Dr. **Felix Post** considered the psychiatry of the aged in some detail. The discussion was enriched by contributions from Dr. H. F. **Maudsley** (Melbourne) who spoke of the need for a social service for old people in Australia. The question whether senile changes can be precipitated or accelerated by an intercurrent trauma was mentioned as arising commonly in medicolegal practice.

PREVENTIVE MEDICINE

President : Dr. **George Buchan**

Preventive Medicine under N.H.S. Act

In a symposium by hospital doctor, general practitioner, and medical officer of health, Dr. H. **Joules** said that the district hospital should provide complete hospital facilities to the people in its area, and should be the centre of teaching not only for medical practitioners but for all health workers. He spoke of the need for preventive medicine in many conditions such as midwifery, gynæcology, tuberculosis, and peptic ulceration. Most of the 400 cases of abortion admitted each year to his own hospital, could have been prevented—not by chasing the abortionist but by ascertaining and correcting the causes.

Dr. W. N. **Pickles** felt that if and when they materialise, health centres will do much to bring the general practitioner into closer touch with the other sections of the profession. He should undertake child-welfare work at the health centre and routine examination of school-children at the health centre or in the homes. The cold, cheerless classroom is no place in which to examine children.

Dr. E. D. **Irvine** said that under the Act the M.O.H. is responsible for the social medical work, including health education and certain clinical aspects of maternity and child welfare. He should regulate admissions to isolation hospitals, tuberculosis sanatoria, and maternity wards, for in most of the cases concerned social conditions are the determining factor. The hardest job under the Act may be to refuse something to the patient. The M.O.H. should act as a link between the hospital, the general practitioner, and the local health service, and he can give the practitioner much help—e.g., such as nursing and home help services. Unfortunately staff shortages will be the limiting factor, and priorities in home nursing will prove troublesome. Dr. Irvine thinks that the importance of the health centres, compared with the primary necessities of life, has been grossly exaggerated. He urged that information about instances, of Wilms's tumour of the kidney by surgery and of suprarenal neuroblastoma by radiotherapy underlines the need for the early diagnosis of abdominal swellings.

---

[2] *Ibid* (in the press).

Radiological diagnosis was reviewed by Dr. C. G. TEALL who emphasised the limitations of radiology in early differential diagnosis, but pointed out that it is better to be unsure early than sure when the patient is beyond aid.

Radiotherapy was discussed by Prof. J. S. MITCHELL, who said that malignant-cell degeneration rather than mitotic inhibition is the object of radiotherapy. There is special danger of producing degenerative vascular changes and katabolic toxic effects in childhood. The radiosensitivity of tumours with identical histology differs widely. He opposes the use of radioactive isotopes in non-malignant conditions in childhood, owing to the danger of long-term degenerative effects.

Dr. A. M. BARRETT said it seemed paradoxical that tumours should be so rare in intra-uterine life when growth is more active than at any other period, and he suggested that tumours are more commonly of multicentric origin than has hitherto been believed.

OPHTHALMOLOGY

President: Mr. O. GAYER MORGAN

Ophthalmic Problems associated with Gynæcological and Obstetric Conditions

Mr. F. A. JULER must have echoed many people's perplexity when he expressed surprise at the infrequency of damage to the eye from obstetric forceps. Long experience as ophthalmologist to Queen Charlotte's Hospital has confronted him with a few babies suffering from conjunctival hæmorrhage and orbital hæmatoma, but he has seen no instance of severe forceps injury to the eye itself. Retinal hæmorrhages, as Mr. Juler has previously pointed out,[1] are not rare in the newborn, but their incidence has never been shown to be raised by the use of obstetric forceps. Such bleeding is presumably due to compression of the chest, and it reminds us of the retinal hæmorrhages found in crush injuries. Hæmorrhage into the retina has also been reported as a consequence of hyperemesis gravidarum, but Mr. Juler regards it as rare. Nor has he often seen puerperal failure of vision. This lamentable sequel of childbirth, so far as can be judged from nineteenth-century textbooks, was relatively common, and arose from postpartum hæmorrhage. Gastro-intestinal and uterine hæmorrhage jointly account for most of the cases in which severe bleeding is followed by optic atrophy, and it seems clear that improved obstetric technique, including antenatal supervision, deserves the credit for stemming postpartum hæmorrhage.

Opposite opinions concerning the efficacy of silver nitrate as a prophylactic against ophthalmia neonatorum have been expressed in recent years. Many clinicians still believe in Credé's method, whereas others regard it as dangerous. At Queen Charlotte's Hospital observations were made on 300 babies. Those of one sex were subjected to silver nitrate instillation at birth, while no drops were used for the others. Subsequent clinical and bacteriological investigation revealed no difference between the two groups, suggesting that silver nitrate has little or no prophylactic value.

Although obstetricians must bear the main responsibility for terminating pregnancy, cases do arise in which an ophthalmologist's opinion may decide the issue. Concerning the significance of retinopathy among expectant mothers, Mr. Juler emphasised that prognosis depends on a number of factors, including the patient's age, the duration of symptoms, and previous attacks. Other speakers mentioned maternal rubella as a reason for emptying the uterus, especially when the infection is acquired during the second month of pregnancy. was suggested, however, that the two epidemics of rubella investigated in Australia near the beginning of the present decade were unusually severe, and that the chances of congenital malformation may well be less among mothers infected with the milder forms of german measles seen in this country.

Speaking of cyclical extragenital bleeding, including hæmorrhage into the conjunctiva and the weeping of sanious tears, Mr. A. R. NUTT remarked that the concept of vicarious menstruation has been questioned, but he asked what other explanation will account for repeated extragenital hæmorrhages at or immediately before the menstrual flow which cease during pregnancy or when the woman attains the menopause. Mr. Nutt suggested that periodical swelling of the pituitary gland offered a possible explanation for menstrual headache. As members of the endocrine orchestra, the ovaries and the pituitary are closely interrelated, and the pituitary might well be influenced by vascular congestion, especially in patients whose sella turcica is of less than the average size.

With regard to the ætiology of iridocyclitis in women, Mr. Juler and Mr. Nutt granted that some cases are tuberculous, but they deprecated the use of systemic injections of tuberculin against local ocular disease—indeed, in their view tuberculin often aggravates an ocular lesion.

Significance and Interpretation of Refraction

Once again refraction has proved a fertile ground for discussion. Mr. E. G. RECORDON deplored the use of small oblique cylinders and other forms of finicky prescription. He urged the need for careful objective examination with the patient's eyes relaxed, and is opposed to the "better or worse" system of subjective testing. Refraction is not a mere sideshow to be grasped within a few months. It should be regarded as an artistic product of experience—not simply mechanical repetition but rather a multitude of tests conducted with critical acumen.

Mr. ARTHUR LISTER contended that so long as a refractionist uses one method efficiently, it does not matter which technique he adopts. The reason why most people laud their own system is that A's failures drift to B's consulting-room, and vice versa—a generalisation which may explain many a series of successful results in other realms of medicine and surgery! Mr. Lister maintains that small refractive errors are seldom important, and that most headaches are not of ocular origin. He laid stress on the importance of taking a history, because refractive changes often represent only one aspect of a deep-seated ocular lesion, and sometimes they point to systemic disease, such as diabetes.

Among the instruments recommended by Mr. VICTOR PURVIS were the streak retinoscope, the focimeter, and the letters of the duochrome test, but he agreed with Mr. Lister's contention that many different roads may lead to the goal of a successful prescription. Both of these observers held that refractive errors are not to blame for styes or conjunctivitis, or for many of the other diseases for which they are often held responsible. Mr. Purvis insisted on speed as well as care in subjective testing. The refractionist must, he said, take charge of the patient.

Occasional Papers

Discussing the Present-day Position of Contact Lenses, Mr. A. G. CROSS reviewed the evolution of technical methods and then considered the contact lens as a form of treatment and as an optical aid. Of 1850 people fitted with contact lenses during the past ten years, a third have since ceased to wear them. Technical advances may augment the proportion of satisfied wearers, by

---

[1] *Trans. ophthal. Soc. U.K.* 1926, 46, 47.

Cross doubts whether it will ever be possible to rantee comfort. Perhaps there will always be a ority in whom conjunctival irritation or œdema of corneal epithelium will render contact lenses olerable.

Mr. J. G. Drummond Currie's thoughtful concern with visual problems of industry is known to those who ard his paper[2] at the 1947 Oxford Ophthalmological ngress. In his present contribution, Optical Aids to the her Man's Job, illustrated with his own drawings. Currie pointed out that magnification is the main inciple in most of the optical aids contrived for lustrial work, but many other devices, such as the ting mirror, could be further exploited.

Speaking of the Heredity of Eye Disease, Mr. B. P. H. attie recalled that many congenital defects formerly ought to be inherited are now known to be transmissible the fœtus by the maternal blood. Therefore it is not ways possible to say whether a given lesion is hereditary environmental. He referred to the various modes of heritance and noted that retinitis pigmentosa may handed down in five different ways.

In his paper on Nutritional Eye Diseases, Mr. Hugh yan dealt chiefly with prisoners in the Far East flicted with nutritional retinopathy. He suggested that lurred vision is the most important initial symptom, nd that ocular changes seldom arise until many months ter nutrition has been curtailed. Central and para- ntral scotomata are the most important field defects, nd a characteristic feature is fragmentation of the otomata during recovery. Restoration of sight is the le in cases where adequate nutrition can be supplied on after the onset of ocular symptoms. Otherwise sting impairment of vision is likely. Mr. Ryan empha- sed the variability of conditions in different camps, nd the corresponding diversity in fundus lesions. The ief ophthalmoscopic signs are obliteration of the foveal flex and macular mottling. Hyperæmia and slight velling of the disc often occur, but Mr. Ryan, aware of ow widely the colour of the disc may vary within normal nits, advised against sweeping deductions when people eak of "slight temporal pallor." Other features occa- onally noted are "broken-stick" (acute bends) and tenuation of the retinal arteries, and turgidity of the rresponding veins. Mr. Ryan contended that the mptoms, field defects, and ophthalmoscopic signs in ese cases preclude the label of "retrobulbar neuritis." he condition should be regarded as a form of retinopathy rought about by capillary dysergia (Stannus). The acula suffers most because of its peculiar pattern of lood-vessels and high oxygen requirement.

NEUROLOGY AND PSYCHIATRY

President: Prof. E. D. Adrian, O.M.

pilepsy of Late Onset

Sir Charles Symonds analysed a series of 130 cases ferred to him because of epileptiform convulsions pearing after the age of thirty. In 56 of them investi- tion supplied no reasonable explanation of the attacks, t 15 of these later proved to have a cerebral tumour. patients with focal epilepsy, air studies, if negative, ould be repeated at intervals. Dr. Denis Williams scribed how the abnormal electro-encephalographic aves which occur during recovery from head injury ay gradually give way to secondary indirect changes ggestive of clinical epilepsy. Mr. D. W. C. Northfield d Dr. James Bull spoke of the help that may be pected, in the early diagnosis of brain tumour, from diography of the skull, air studies, and arteriography.

nile Deterioration

From his survey of 477 old people in Wolverhampton r. J. H. Sheldon gave an account of the various symptoms which may cause incapacity in the elderly. Common complaints include difficulty in getting about in the dark, fears of traffic, weakness, vertigo, and falls. The inner ear seems to be unusually sensitive to involutional changes, more especially in men. Dr. Macdonald Critchley discussed the problem of when involutional changes actually start, and the question whether old age is a normal physiological activity, a pathological process, or both. Though wisdom does not necessarily come with age, compulsory retirement at 60 or 65 deprives the community of an important asset—the accumulated experience and intelligence of people in their seventh and eighth decades. The span of healthy life may yet be expanded; and among factors that reduce it he included tobacco, which, he said, seems to shorten the expectation of life in direct proportion to the amount smoked.

Mrs. A. V. Hill, speaking as one of the laity with a close knowledge of old folks' homes, divided the aged into (1) cases of senile dementia, (2) persons of weak intellect who have grown old, (3) the "aged crank," and (4) patients with simple senility. Trained nurses do not make the ideal attendants, and the discipline of the sickroom is unnecessarily irksome to the aged. Dr. Trevor Howell dealt with some of the physical and mental concomitants of ageing, while Dr. Felix Post considered the psychiatry of the aged in some detail. The discussion was enriched by contributions from Dr. H. F. Maudsley (Melbourne) who spoke of the need for a social service for old people in Australia. The question whether senile changes can be precipitated or accelerated by an intercurrent trauma was mentioned as arising commonly in medicolegal practice.

PREVENTIVE MEDICINE

President: Dr. George Buchan

Preventive Medicine under N.H.S. Act

In a symposium by hospital doctor, general practitioner, and medical officer of health, Dr. H. Joules said that the district hospital should provide complete hospital facilities to the people in its area, and should be the centre of teaching not only for medical practitioners but for all health workers. He spoke of the need for preventive medicine in many conditions such as midwifery, gynæcology, tuberculosis, and peptic ulceration. Most of the 400 cases of abortion admitted each year to his own hospital, could have been prevented—not by chasing the abortionist but by ascertaining and correcting the causes.

Dr. W. N. Pickles felt that if and when they materialise, health centres will do much to bring the general practitioner into closer touch with the other sections of the profession. He should undertake child-welfare work at the health centre and routine examination of school-children at the health centre or in the homes. The cold, cheerless classroom is no place in which to examine children.

Dr. E. D. Irvine said that under the Act the M.O.H. is responsible for the social medical work, including health education and certain clinical aspects of maternity and child welfare. He should regulate admissions to isolation hospitals, tuberculosis sanatoria, and maternity wards, for in most of the cases concerned social conditions are the determining factor. The hardest job under the Act may be to refuse something to the patient. The M.O.H. should act as a link between the hospital, the general practitioner, and the local health service, and he can give the practitioner much help—e.g., such as nursing and home help services. Unfortunately staff shortages will be the limiting factor, and priorities in home nursing will prove troublesome. Dr. Irvine thinks that the importance of the health centres, compared with the primary necessities of life, has been grossly exaggerated. He urged that information about instances, of Wilms's tumour of the kidney by surgery and of suprarenal neuroblastoma by radiotherapy underlines the need for the early diagnosis of abdominal swellings.

---

[2] *Ibid* (in the press).

Radiological diagnosis was reviewed by Dr. C. G. **Teall** who emphasised the limitations of radiology in early differential diagnosis, but pointed out that it is better to be unsure early than sure when the patient is beyond aid.

Radiotherapy was discussed by Prof. J. S. **Mitchell**, who said that malignant-cell degeneration rather than mitotic inhibition is the object of radiotherapy. There is special danger of producing degenerative vascular changes and katabolic toxic effects in childhood. The radiosensitivity of tumours with identical histology differs widely. He opposes the use of radioactive isotopes in non-malignant conditions in childhood, owing to the danger of long-term degenerative effects.

Dr. A. M. **Barrett** said it seemed paradoxical that tumours should be so rare in intra-uterine life when growth is more active than at any other period, and he suggested that tumours are more commonly of multicentric origin than has hitherto been believed.

OPHTHALMOLOGY

President: Mr. O. **Gayer Morgan**

Ophthalmic Problems associated with Gynæcological and Obstetric Conditions

Mr. F. A. **Juler** must have echoed many people's perplexity when he expressed surprise at the infrequency of damage to the eye from obstetric forceps. Long experience as ophthalmologist to Queen Charlotte's Hospital has confronted him with a few babies suffering from conjunctival hæmorrhage and orbital hæmatoma, but he has seen no instance of severe forceps injury to the eye itself. Retinal hæmorrhages, as Mr. Juler has previously pointed out,[1] are not rare in the newborn, but their incidence has never been shown to be raised by the use of obstetric forceps. Such bleeding is presumably due to compression of the chest, and it reminds us of the retinal hæmorrhages found in crush injuries. Hæmorrhage into the retina has also been reported as a consequence of hyperemesis gravidarum, but Mr. Juler regards it as rare. Nor has he often seen puerperal failure of vision. This lamentable sequel of childbirth, so far as can be judged from nineteenth-century textbooks, was relatively common, and arose from postpartum hæmorrhage. Gastro-intestinal and uterine hæmorrhage jointly account for most of the cases in which severe bleeding is followed by optic atrophy, and it seems clear that improved obstetric technique, including antenatal supervision, deserves the credit for stemming postpartum hæmorrhage.

Opposite opinions concerning the efficacy of silver nitrate as a prophylactic against ophthalmia neonatorum have been expressed in recent years. Many clinicians still believe in Credé's method, whereas others regard it as dangerous. At Queen Charlotte's Hospital observations were made on 300 babies. Those of one sex were subjected to silver nitrate instillation at birth, while no drops were used for the others. Subsequent clinical and bacteriological investigation revealed no difference between the two groups, suggesting that silver nitrate has little or no prophylactic value.

Although obstetricians must bear the main responsibility for terminating pregnancy, cases do arise in which an ophthalmologist's opinion may decide the issue. Concerning the significance of retinopathy among expectant mothers, Mr. Juler emphasised that prognosis depends on a number of factors, including the patient's age, the duration of symptoms, and previous attacks. Other speakers mentioned maternal rubella as a reason for emptying the uterus, especially when the infec is acquired during the second month of pregnancy. was suggested, however, that the two epidemics rubella investigated in Australia near the beginning the present decade were unusually severe, and that th chances of congenital malformation may well be l among mothers infected with the milder forms of germ measles seen in this country.

Speaking of cyclical extragenital bleeding, includ hæmorrhage into the conjunctiva and the weeping sanious tears, Mr. A. R. **Nutt** remarked that the concep of vicarious menstruation has been questioned, but h asked what other explanation will account for repeated extragenital hæmorrhages at or immediately before the menstrual flow which cease during pregnancy or when the woman attains the menopause. Mr. Nutt suggested that periodical swelling of the pituitary gland offered a possible explanation for menstrual headache. As members of the endocrine orchestra, the ovaries and the pituitary are closely interrelated, and the pituitary might well be influenced by vascular congestion, especially in patients whose sella turcica is of less than the average size.

With regard to the ætiology of iridocyclitis in women. Mr. Juler and Mr. Nutt granted that some cases are tuberculous, but they deprecated the use of systemic injections of tuberculin against local ocular disease—indeed, in their view tuberculin often aggravates an ocular lesion.

Significance and Interpretation of Refraction

Once again refraction has proved a fertile ground for discussion. Mr. E. G. **Recordon** deplored the use of small oblique cylinders and other forms of finicky prescription He urged the need for careful objective examination with the patient's eyes relaxed, and is opposed to th "better or worse" system of subjective testing. Refraction is not a mere sideshow to be grasped within a fe months. It should be regarded as an artistic prod of experience—not simply mechanical repetition b rather a multitude of tests conducted with critic acumen.

Mr. **Arthur Lister** contended that so long as a refractionist uses one method efficiently, it does not matter which technique he adopts. The reason why most people laud their own system is that A's failures drift to B's consulting-room, and vice versa—a generalisation which may explain many a series of successful results in other realms of medicine and surgery! Mr. Lister maintains that small refractive errors are seldom important, and that most headaches are not of ocular origin He laid stress on the importance of taking a history, because refractive changes often represent only one aspect of a deep-seated ocular lesion, and sometimes they point to systemic disease, such as diabetes.

Among the instruments recommended by Mr. **Victor Purvis** were the streak retinoscope, the focimeter, and the letters of the duochrome test, but he agreed with Mr. Lister's contention that many different roads may lead to the goal of a successful prescription. Both these observers hold that refractive errors are not blame for styes or conjunctivitis, or for many of the oth diseases for which they are often held responsib Mr. Purvis insisted on speed as well as care in subjectiv testing. The refractionist must, he said, take charge the patient.

Occasional Papers

Discussing the Present-day Position of Contact Lense Mr. A. G. **Cross** reviewed the evolution of technical methods and then considered the contact lens as a form of treatment and as an optical aid. Of 1850 people fitted with contact lenses during the past ten years, third have since ceased to wear them. Technical advance may augment the proportion of satisfied wearers, but e been tapped; and he mentioned in particular the nomenon of interference first observed in the study plant viruses.

---

[1] *Trans. ophthal. Soc. U.K.* 1926, 46, 47.

rof. **Ronald Hare** referred to the possibility of in variations somewhat analogous to smooth and rough ains in bacteria; this was hinted at in Burnet's earlier rk and may be related to problems of prophylaxis. aking of the mass production of viruses for prophy-is by egg inoculation, he suggested that in the present te of knowledge, and with existing rationing trictions, the vast number of eggs which would be uired could perhaps be used to better advantage.

Prof. **W. I. B. Beveridge** would have none of Professor re's gloom, claiming that much that is already known ld be used with profit. Among other arresting ints, he mentioned the specific blocking effect of the iedländer polysaccharide on the virus of mumps.

Dr. **M. G. P. Stoker** concluded with a short survey the problems of vaccination against smallpox; and ce again the problem of "blocking" and interference ose, bearing, as it does, on the relation of the effective-ss of a given batch of vaccine to the behaviour of the tive and inactive particles in that batch. Throughout e discussion the theme of interference and specific ocking continued, offering a new field of research in our tack on virus prophylaxis.

ther Communications and Demonstrations

Dr. **K. C. Dixon** produced a stimulating paper on the fects of glucose and oxygen deprivation on the leakage potassium from the living cell. Though the observa- ons are not new, they afford an excellent example of a ndamental approach too often neglected. Dr. N. H. **ARTIN**'s communication on electrophoretic fractiona- ion and the light it throws on disease processes in eneral provoked an animated discussion. Demonstra- ons were mounted both at the Strangeways Laboratory, here Miss **Honor Fell**, D.SC., and her group gave an xcellent survey of the work being done there, and in he department of pathology where the beautiful sections repared by Dr. **J. Gough** and Dr. **J. E. Wentworth** howed how much can still be learnt from careful xaminations of macroscopic specimens.

ANÆSTHETICS

President: Dr. Z. **Mennell**

næsthesia for Chest Surgery

The anæsthetist, said Dr. **Joan Millar**, can now rovide operating conditions satisfactory to both patient nd surgeon, so that the latter is no longer hindered by ck of time. Three essential factors are the main-enance of an airway, the prevention of anoxia, and the placement of blood as it is lost: the particular anæs- etic agent used is of less importance than practical nowledge and experience. Careful preoperative pre- aration and assessment of cardiac and respiratory nction are required. Local analgesia is used for ndoscopy, for drainage of empyemas and lung abscesses, nd in the surgery of pulmonary tuberculosis. (In xtrafascial apicolysis unilateral vagal block at the base f the skull is useful to prevent coughing.) For lung section—which is now possible in any case of pulmonary ppuration provided the extent of the disease does not reclude surgery—Dr. Millar recommended general næsthesia. Controlled and assisted respiration are best served for the experienced anæsthetist. Useful though rare may be, it is liable to cause residual muscular eakness and a reduction in tidal exchange, and thus redispose to postoperative atelectasis. Rapid restora- on of normal respiratory function is the aim, and mmediate bronchoscopic aspiration should be under- ken if need be. In difficult cases radiography imme- ately after operation is useful to reveal pneumothorax r atelectasis.

Dr. **E. H. Rink** related his experiences as anæsthetist in 50 cases of congenital pulmonary stenosis treated surgically. There were 8 deaths within six hours, and 1 later; but the results more than justified the operation. Though it might last five hours, and the children were mostly undersized and of poor resistance, they stood it well. Cyclopropane or ether was given through an endotracheal tube with controlled respiration.

Dr. **G. S. W. Organe**, Dr. **T. C. Gray**, and Dr. **H. H. Pinkerton** all questioned whether, for thoracoplasty, local analgesia is really preferable to general anæsthesia. Curare, said Dr. Gray, enables the operation to be done under very light narcosis.

Abdominal Relaxation

The three requirements of an abdominal anæsthetic, said Dr. **C. B. Lewis**, are safety, the best conditions for operating, and the comfort of the patient. Spinal anæsthesia fulfils all three, and Dr. Lewis, though previously sceptical, has lately been much impressed by its use, supplemented by 'Thiopentone' to secure and maintain unconsciousness, in 100 cases of gastrectomy, in only 1 of which the blood-pressure fell seriously. Though ether remains the safest and best anæsthetic for children under 12, full relaxation can be obtained only by saturating the patient, and the recovery phase may be extremely unpleasant. Intravenous thiopentone, in sufficient quantity to get relaxation, carries risk. The greatest advance in anæsthesia since the intravenous barbiturates is curare, but during long operations the multiple injections give uneven results. Using curare, great caution is needed with a heavily built patient in a steep Trendelenburg position, for the abdominal contents press on the thorax. In Dr. Lewis's opinion intubation is the most valuable aid to relaxation, especially in the upper-abdominal case where complete control of the airway is essential. In the average abdominal case any one of three methods can provide perfect relaxation, and skill is more important than the choice of agent.

Dr. **Agnes Gray** pointed out that in the gastrectomy series quoted thiopentone was given: the good results merely proved that the patients could stand a spinal anæsthetic besides their gastrectomy. Dr. **Robert Cope**, recalling the Portsmouth cases of meningitis, felt that spinal anæsthesia should be restricted to clinics where the technique of sterilisation and the technique of operation are beyond all criticism. Dr. **Ronald Jarman**, having given some 18,000 spinals, thought that the method has its place; but for every 2 spinals he now gives 5 curares.

Several members referred to 'Myanesin.' Dr. **H. R. Youngman** attributed its hæmolytic effect solely to the solvent in which it is given, and he doubted whether the last has been heard of it, or of some similar drug. Dr. **R. F. Woolmer** was one of several speakers who insisted that patients in the Trendelenburg position should not hang from the knees. Not only does this encourage thrombosis and embolism (which Mr. **Bryan Williams** described as the main cause of morbidity and mortality after gynæcological operations), but it prevents relaxation of the recti. On the other hand, brachial-plexus palsy caused by shoulder-rests must be avoided.

Caudal Extradural Block

Dr. **G. C. Steel** said that though caudal block is best known as a means of producing continuous analgesia in midwifery it has other uses—e.g., in the treatment of phlegmasia alba dolens, eclamptic convulsions, and anuria; for the pain of inoperable cancer; and for estimating the effects of sympathectomy. Dr. Steel would not say that it is preferable to spinal analgesia; but he feels happier outside the theca than inside it. Though not supposed to affect motor power appreciably, caudal block is particularly useful in vaginal hysterectomy, giving both relaxation and an avascular field.

sickness should be more fully transferable than at present and that it should all be collated in the health office.

In the discussion, Mr. H. J. McCURRICH contended that all the larger hospitals should become teaching centres for doctors, nurses, and ancillaries. The family doctor should have ready access to his patients in hospital but should not undertake treatment. He feared that the difficulty of recruiting nurses will increase, for nursing cannot compete with other occupations in amenities. In publicity campaigns, therefore, the appeal should be to ideals and not to creature comforts. Dr. JEAN MACKINTOSH felt that the M.O.H. should assist in assessing priority where maternity beds are short. In her view it is not sufficient for local-authority medical officers to attend at outpatient departments and ward rounds; they should have actual clinical care of patients in hospital.

Poliomyelitis

Dr. WILLIAM GUNN said that in the present century, and particularly in recent decades, poliomyelitis seems to have acquired special malignant characteristics expressed in periodical explosive prevalence and high clinical severity. Active and passive immunisation methods have found little place in prevention or treatment. Vaccines have proved ineffective or dangerous. Passive immunisation with serum is applicable only in certain cases, for the attack-rate following exposure is normally low and the period of immunity afforded by serum is only about three weeks. He felt that the greatest success up to now has been attained by measures directed against infection by droplet nuclei—restriction of travel, prevention of close assembly, and segregation of possible carriers. Strict personal hygiene, avoidance of fatigue, and avoidance of respiratory infections are important. It is perhaps significant, he said, that the largest epidemic in our history, in 1947, coincided with one of the hottest summers on record.

Dr. F. W. BUNTING favours more rigid isolation of actual cases and avoidance of large assemblies—particularly children's film matinées which he described as a "Clapham Junction for virus dissemination."

Dr. STANLEY BANKS pointed out that present notifications may give a false impression, since they include abortive cases, whereas formerly only the paralytic cases were actually brought to notice. He questioned the value of the complement-fixation test: people contract poliomyelitis who have previously shown a high titre of agglutinins. He criticised administrative instructions issued by the Ministry of Health and medical officers of health. In his opinion the prohibition of tonsillectomy during epidemics is the only useful preventive measure. Dr. J. ALISON GLOVER thought that every M.O.H. should pay frequent visits to swimming-baths; but the bad ventilation rather than the water is the danger. Isolation of carriers he regards as impracticable.

Morbidity Statistics

Dr. P. L. McKINLAY asked for more extensive sickness records, because he believes much of the present sickness is preventable. Far too little attention is paid by medical officers of health and others to the value of statistics, which are a record of progress and a guide to action. The Ministry of National Insurance records should prove to be a wonderful source of information. The conditions causing incapacity for work are very different from those producing death. The most common of them are respiratory catarrh, rheumatism, superficial septic conditions, gastric disturbances, and general debility. The death-rate is falling, but chronic incapacity is increasing. Many people are being kept alive but are not functioning as useful members of the working community. Hospital records are too selective to give a true picture of the morbidity-rates in the general population.

Dr. J. MADDISON said that the M.O.H. should be to get the help of a team of investigators—r medical officers, a statistician, clerical assistants, p card machinery, calculating machine, and field work for special inquiries. Just as today he refers his cli cases to the appropriate doctor, so then he could re his statistical and research problems to a team of ex

PATHOLOGY AND BACTERIOLOGY

President: Prof. H. R. DEAN

After a graceful welcome from Professor DEAN, the first session opened with a discussion of advances i knowledge of the Rh factor and their implications.

Rhesus Factor

Prof. D. F. CAPPELL spoke of the risks of i- immunisation of the Rh—ve mother by the Rh+v foetus and commented that, while ABO incompatibility of itself rarely produces such a dramatic picture, i- immunisation of the mother is significantly less when the ABO groups of mother and child are compatible. From his own observations the hæmolytic anæmia produced i the presence of the "incomplete" or "blocking" antibodies is not significantly different from that found i the presence of the complete antibodies. He urged clarification of nomenclature on the basis of Fisher's classical work and the dropping of the alternative.

Dr. P. L. MOLLISON, in a practical survey of the treatment of hæmolytic disease of the newborn, emphasised the difficulty in this country of comparing present results with results before 1943 when Coombs's test came into use, or with results in other countries where that test is still not used widely. He stressed the value of exchange transfusion, and showed that a more rapid exchange of erythrocytes may be achieved by using slightly concentrated erythrocyte suspension.

To round off a well-balanced discussion, Mr. R. R. COOMBS, PH.D., regaled the section with an account of his investigations into the intricacies of hæmolytic disease of newborn foals and—even more important— his studies in rabbits, demonstrating anew the lessons to be learned from other mammals.

Thymus in Myasthenia Gravis

Dr. A. B. BRATTON recalled that morbid-anatomic assessment does not support the view that persistence of the thymus is associated significantly with myasthenia gravis. He admitted, however, that a number of myasthenics on whom thymectomy was performed had immediate and protracted remissions after operation— the reason remaining obscure. Of 70 specimens of thymus from myasthenia cases 11 showed neoplasia

Streptomycin

Dr. M. H. GLEESON-WHITE followed with a brief account of 4 cases of meningitis caused by *Hæmophilus influenzæ* of the Pitman B strain which were treated with streptomycin. Success was attained in 3, but the 4th relapsed and the organism showed enhanced resistance to streptomycin. No toxic manifestations were encountered though full intrathecal and intramuscular dosage was used.

Hepatitis

Dr. G. W. M. FINDLAY quoted Peter Martyr, whose works, published in 1595, seem to have been a complete anticipation of many of the recent reports on the part of nutritional deficiency in the production of hepatic lesions. In the general discussion Dr. J. N. P. DAV (Uganda) and Dr. GILLMAN (Johannesburg) interesting and suggestive observations on the association of endocrine disturbance with liver damage—w seems to open a field for more general study of relationship of cholesterol metabolism to liver damage

Prophylaxis of Virus Infections

Dr. C. H. ANDREWES, F.R.S., said that by no m all the potential approaches to wholesale prophyl e been tapped: and he mentioned in particular the nomenon of interference first observed in the study plant viruses.

Prof. **RONALD HARE** referred to the possibility of ain variations somewhat analogous to smooth and rough ains in bacteria; this was hinted at in Burnet's earlier rk and may be related to problems of prophylaxis. eaking of the mass production of viruses for prophyis by egg inoculation, he suggested that in the present te of knowledge, and with existing rationing trictions, the vast number of eggs which would be quired could perhaps be used to better advantage.

Prof. **W. I. B. BEVERIDGE** would have none of Professor re's gloom, claiming that much that is already known uld be used with profit. Among other arresting ints, he mentioned the specific blocking effect of the iedländer polysaccharide on the virus of mumps.

Dr. **M. G. P. STOKER** concluded with a short survey the problems of vaccination against smallpox: and ice again the problem of "blocking" and interference ose, bearing, as it does, on the relation of the effectivess of a given batch of vaccine to the behaviour of the tive and inactive particles in that batch. Throughout ie discussion the theme of interference and specific locking continued, offering a new field of research in our ttack on virus prophylaxis.

ther Communications and Demonstrations

Dr. **K. C. DIXON** produced a stimulating paper on the ffects of glucose and oxygen deprivation on the leakage f potassium from the living cell. Though the observaions are not new, they afford an excellent example of a undamental approach too often neglected. Dr. **N. H. IARTIN**'s communication on electrophoretic fractionaion and the light it throws on disease processes in eneral provoked an animated discussion. Demonstraons were mounted both at the Strangeways Laboratory, here Miss **HONOR FELL**, D.SC., and her group gave an xcellent survey of the work being done there, and in ne department of pathology where the beautiful sections repared by Dr. **J. GOUGH** and Dr. **J. E. WENTWORTH** nowed how much can still be learnt from careful xaminations of macroscopic specimens.

ANÆSTHETICS

President: Dr. Z. MENNELL

næsthesia for Chest Surgery

The anæsthetist, said Dr. **JOAN MILLAR**, can now rovide operating conditions satisfactory to both patient nd surgeon, so that the latter is no longer hindered by ick of time. Three essential factors are the mainenance of an airway, the prevention of anoxia, and the eplacement of blood as it is lost: the particular anæsietic agent used is of less importance than practical nowledge and experience. Careful preoperative prearation and assessment of cardiac and respiratory unction are required. Local analgesia is used for ndoscopy, for drainage of empyemas and lung abscesses, nd in the surgery of pulmonary tuberculosis. (In xtrafascial apicolysis unilateral vagal block at the base the skull is useful to prevent coughing.) For lung section—which is now possible in any case of pulmonary uppuration provided the extent of the disease does not reclude surgery—Dr. Millar recommended general næsthesia. Controlled and assisted respiration are best served for the experienced anæsthetist. Useful though urare may be, it is liable to cause residual muscular eakness and a reduction in tidal exchange, and thus redispose to postoperative atelectasis. Rapid restoraon of normal respiratory function is the aim, and nmediate bronchoscopic aspiration should be underaken if need be. In difficult cases radiography immeiately after operation is useful to reveal pneumothorax r atelectasis.

Dr. **E. H. RINK** related his experiences as anæsthetist in 50 cases of congenital pulmonary stenosis treated surgically. There were 8 deaths within six hours, and 1 later; but the results more than justified the operation. Though it might last five hours, and the children were mostly undersized and of poor resistance, they stood it well. Cyclopropane or ether was given through an endotracheal tube with controlled respiration.

Dr. **G. S. W. ORGANE**, Dr. **T. C. GRAY**, and Dr. **H. H. PINKERTON** all questioned whether, for thoracoplasty, local analgesia is really preferable to general anæsthesia. Curare, said Dr. Gray, enables the operation to be done under very light narcosis.

Abdominal Relaxation

The three requirements of an abdominal anæsthetic, said Dr. **C. B. LEWIS**, are safety, the best conditions for operating, and the comfort of the patient. Spinal anæsthesia fulfils all three, and Dr. Lewis, though previously sceptical, has lately been much impressed by its use, supplemented by 'Thiopentone' to secure and maintain unconsciousness, in 100 cases of gastrectomy, in only 1 of which the blood-pressure fell seriously. Though ether remains the safest and best anæsthetic for children under 12, full relaxation can be obtained only by saturating the patient, and the recovery phase may be extremely unpleasant. Intravenous thiopentone, in sufficient quantity to get relaxation, carries risk. The greatest advance in anæsthesia since the intravenous barbiturates is curare, but during long operations the multiple injections give uneven results. Using curare, great caution is needed with a heavily built patient in a steep Trendelenburg position, for the abdominal contents press on the thorax. In Dr. Lewis's opinion intubation is the most valuable aid to relaxation, especially in the upper-abdominal case where complete control of the airway is essential. In the average abdominal case any one of three methods can provide perfect relaxation, and skill is more important than the choice of agent.

Dr. **AGNES GRAY** pointed out that in the gastrectomy series quoted thiopentone was given: the good results merely proved that the patients could stand a spinal anæsthetic besides their gastrectomy. Dr. **ROBERT COPE**, recalling the Portsmouth cases of meningitis, felt that spinal anæsthesia should be restricted to clinics where the technique of sterilisation and the technique of operation are beyond all criticism. Dr. **RONALD JARMAN**, having given some 18,000 spinals, thought that the method has its place; but for every 2 spinals he now gives 5 curares.

Several members referred to 'Myanesin.' Dr. **H. R. YOUNGMAN** attributed its hæmolytic effect solely to the solvent in which it is given, and he doubted whether the last has been heard of it, or of some similar drug. Dr. **R. F. WOOLMER** was one of several speakers who insisted that patients in the Trendelenburg position should not hang from the knees. Not only does this encourage thrombosis and embolism (which Mr. **BRYAN WILLIAMS** described as the main cause of morbidity and mortality after gynæcological operations), but it prevents relaxation of the recti. On the other hand, brachial-plexus palsy caused by shoulder-rests must be avoided.

Caudal Extradural Block

Dr. **G. C. STEEL** said that though caudal block is best known as a means of producing continuous analgesia in midwifery it has other uses—e.g., in the treatment of phlegmasia alba dolens, eclamptic convulsions, and anuria: for the pain of inoperable cancer; and for estimating the effects of sympathectomy. Dr. Steel would not say that it is preferable to spinal analgesia; but he feels happier outside the theca than inside it. Though not supposed to affect motor power appreciably, caudal block is particularly useful in vaginal hysterectomy, giving both relaxation and an avascular field.

It is useful in terminating pregnancy where inhalation anæsthesia is inadvisable: the evacuated uterus contracts remarkably quickly. Though only a small specialised weapon, it has its place.

Dr. A. R. HUNTER felt that the results of sympathectomy for hypertension are such as to make it doubtful whether they are worth evaluating. Epidural cellulitis, he said, can be as dangerous as meningitis. Dr. GRAY spoke of collapse, with sudden fall of blood-pressure, when the block goes too high. Such collapse Dr. STEEL attributed to persisting with the caudal block after getting a "bloody tap."

Intubation in Childhood

Dr. ROBERT COPE explained that in infants the laryngeal aperture is tiny, and an intratracheal tube must be introduced slowly. He reviewed the various stages of early life at which this may be necessary, from the relief of asphyxia neonatorum onwards. In the first few days, when operating on some major abnormality, a perfect airway may make all the difference. In the operations of the first few weeks—for pyloric stenosis, duodenal atresia, or intussusception—a tube allows anæsthesia to be lightened without laryngeal spasm.

Analgesia in Midwifery was discussed jointly with the section of obstetrics and gynæcology (see below).

OBSTETRICS AND GYNÆCOLOGY

President: Mr. J. R. CAMPBELL-CANNEY

Infertility

To prevent the great unhappiness caused to so many couples by sterility Dr. BETHEL SOLOMONS advocated premarital tests. His opening paper covered the whole subject of infertility, but two facts in particular emerged —firstly, that he puts male responsibility as high as 50%, and secondly that deaths *do* occur from insufflation of the fallopian tubes. The danger of gas embolism is greatest with oxygen and air, but he has seen a death during insufflation with carbon dioxide. It is a duty, he said, to publish fatal cases of this kind. Mr. ALBERT SHARMAN held that for uterotubal insufflation only carbon dioxide should be used: he advised that insufflation should take place in the premenstrual phase, when a premenstrual biopsy can be performed after it.

Mr. KENNETH WALKER's main theme was the importance of complete examination of semen specimens; but he also dwelt on the abnormalities associated with ejaculation and mentioned the possibility of retrograde ejaculation into the bladder, as occurs after prostatectomy. He made a plea for the wider use by gynæcologists of the post-coital test, which is, after all, the final test of the man's ability to impregnate his wife.

Mr. PERCY MALPAS dealt with the difficult subject of recurrent abortion. He thinks that perhaps we have over-emphasised the hormonal factor. Apart from cases where a well-defined organic basis can be found, such as renal disease or some local abnormality, he contended that abnormalities of the nervous system, affecting uterine quiescence, are mainly responsible for habitual abortion in the first few months of pregnancy. If a sustained nervous inhibition is the means by which the pregnant uterus is normally kept quiescent, rest should be the main therapeutic agent in these cases.

Mr. CECIL BINNEY, a barrister-at-law, brought his expert legal mind to bear on the subject of artificial insemination. He argued that artificial insemination with donated semen cannot be used as grounds for divorce, since it cannot be interpreted as an act of adultery. (Adultery is a sexual act, which has nothing to do with the conception of a child, and birth of a child without a sexual act can hardly be adultery.) Nor can artificial insemination be used as grounds for divorce in relation to nullity. On the other hand donor insemination introduces almost insuperable difficulties in conne with the law of inheritance of settled funds. In subsequent lively discussion on this, as on other aspe of insemination, the general view seemed to be that practice should be left to somebody else.

The frequency with which pregnancy follows adopt of a child led to the suggestion that babies might b borrowed for the specific purpose of relaxing tension an stimulating mother-love. Fanciful though this may b the meeting was left with the feeling that there are mo things in heaven and earth than are dreamt of in o philosophy; members were reminded that in assessing results in the cure of infertility they must be humble because nature herself so often cures without human ai

Analgesia in Midwifery

Prof. W. C. NIXON opened the second discussion wit an inspiring paper which went far beyond the consideration of particular analgesics or anæsthetics. He pointed out that the more complete the antenatal preparatio of the patient, the more physiological her labour wil be and the less pain she will have. The relief of pai in the labour ward should begin in the antenatal clinic. Confidence thus inspired in the patient goes a long way towards removing fear and inhibitions that ultimately impede the natural processes of childbirth. Professor Nixon spoke also of the need for sleep during labour, especially at the natural time for sleeping at night, and discussed the various drugs that might be used to promote it. He discouraged the use of barbiturates, but from further experience at University College Hospital he advised the use of pethidine in doses of 150 mg. At this hospital investigations are being carried out by full-time research anæsthetist appointed to the obstetr department, and this is a development in hospital organisation that other units should pursue. On if obstetricians and anæsthetists work together satisfactory team-work be attained and the pati be legitimately relieved of unnecessary pain.

The next speakers were Dr. P. J. HELLIWELL Dr. A. M. HUTTON, both of whom are working with research grant at Guy's Hospital. Reporting at so length on their investigations with 'Trilene' in midwifery they concluded that the danger of the self-administere trilene inhalers is by no means negligible, and that th patient should never be left alone with a self-administering trilene inhaler. The value of trilene in midwifery is nevertheless very considerable, and the general vie is that it is the most useful supplement for gas-and-oxygen or gas-and-air. During the discussion chloroform received many bouquets from experienced and older practitioners, and caudal analgesia was mentioned as very valuable in carefully selected cases and in experienced hands.

The Third Stage and its Complications

The third stage of labour appropriately occupied th final stage of the section's meetings.

Mr. J. D. S. FLEW put in a strong plea for the use oxytocic drugs—ergometrine in particular—before t delivery of the placenta in cases of hæmorrhage. siderable changes are nowadays being made in management of the third stage, both normal abnormal. In particular the older teaching of Cr expression and bimanual compression is now recogni as often dangerous and productive of shock. This a vitally important point, because midwives up and do the country are still being taught manual removal the conscious patient—a method which they would ne carry out in practice—as well as Credé expressio Far less harm would be done if they were allowed to g an oxytocic drug to control immediate hæmorrhag Later speakers all agreed with Mr. Flew in condemni the old-fashioned methods of expressing the placent which can often far more safely be expressed from th ver segment of the uterus and upper vagina by supra-bic pressure and gentle traction on the cord than by shing the uterus down into the pelvis. The shock oduced by the Credé expression is apparent to all, d it is time that the third stage of labour was rewritten the textbooks.

Prof. H. L. SHEEHAN's work on obstetric shock was ell known to his audience, and he explained many the facts he has demonstrated in published papers. e two outstanding facts that emerged from his experi-ce are that death may be caused by traumatic pro-dures undertaken for the removal of the placenta and so by undue prolongation of the third stage of labour. he answer seems to be that manual removal of the acenta under surgical anæsthesia is far safer, because ss traumatic, than repeated Credé expression. Now at the danger from sepsis is so much less, manual moval of the placenta need no longer be regarded a last resort for the dying.

Finally, Dr. P. L. MOLLISON spoke of the importance f the rhesus factor in relation to the third stage of bour. Administration of Rh-positive blood to a h-negative woman not only may endanger her life mmediately but also makes it highly probable that in ny subsequent pregnancy her baby will be affected by æmolytic disease. For this reason if no other, routine esting of all pregnant women for the rhesus factor desirable. Investigation of cord blood from babies uspected of hæmolytic disease is also necessary.

MISAPPREHENSIONS ABOUT N.H.S.

IN a speech at Preston on July 5, the opening day of he National Health Service, Mr. Aneurin Bevan, inister of Health, spoke of misapprehensions about the ervice and made the following statements:

1. No insurance qualification is necessary.
2. There is *no* obligation on patients to take advantage of e scheme—they can use it or not, as they prefer, but we elieve that soon nearly everyone will be using it. The more niversal it becomes, the more successful it will be.
3. There is *no* limit to either the cost or the quality of the rugs which may be prescribed under the scheme, provided hat they are necessary.
4. There is *no* rule that a doctor must not visit patients n their homes unless their condition requires it. He is free o visit when he likes—and under an obligation to do so when he patient's condition makes this necessary. (On the other and, patients are expected to attend at the surgery when they an.)
5. There is *no* rule that doctors cannot see patients by ppointment. We hope they will do so as much as they can.
6. Doctors must not accept any payment for treatment iven to patients on their public lists. To do so would be a reach of their terms of service, for which there might be a enalty.
7. There are some doctors who are reported to be telling ome of their patients that they will accept them as paying atients but not under the National Health Service. Such onduct is of course a complete abuse of the doctor's right f free choice of patient; and those doctors who are guilty f it will be condemned by their colleagues as a disgrace to heir profession.

He added that there were three ways in which all could elp the new service: (1) by coöperation between all oncerned in the scheme—practitioners, patients, and dministrators; (2) by approaching the service with the etermination to make it work well; and (3) by not ushing for treatment which is not urgent in the early ays of the scheme. According to the *Manchester uardian*, he claimed that there had been no political ias in his selection of people to take part in the voluntary achinery. He had achieved that universal measure of isagreement that was evidence of complete impartiality, nd already a team spirit had grown up. He had a brief, but utterly sincere word of thanks" for all who ad done the voluntary work of the past and had handed ver so much that was a good going concern.

In England Now

A Running Commentary by Peripatetic Correspondents

JULY 5.—For the first time in local memory, the surgery is empty on a Monday morning; and after reading "Question Time" in Parliament that is about the only thing that could still surprise me.

Apart from a few telephone inquiries from people who heard about the service from Mr. Attlee for the first time, and one pessimist who wanted to know whether registering with three doctors would assure the attention of one, there is only the steady drip of cards —now apologetically and unobtrusively pushed through the letter box—to give one something to do for a living. Omitting wealthy over-eighties, only one patient has so far paid me the doubtful compliment of wishing to remain private. I suppose she imagines that I visit her in the mornings because she likes to take the dogs for a walk in the afternoons and can afford to pay for her fancies. But, if she only knew, the visiting-list will be compiled exactly as before, according to urgency first, physical condition second, and convenience third. Though placed third, the convenience of the patient always *has* been studied as a matter of course: one would not dream of asking a mother with a young family to waste her time waiting about in the surgery, nor would one think of visiting her at the baby's feeding-times if this can be avoided. It seems to me more important to stress this than to manufacture a hard and fast distinction between the two categories of patients so as to give the private patient something tangible to pay for.

It would be a pity if attention to the patient's convenience became a marketable commodity which people felt they could not expect within the service. They have, alas, assimilated this idea all too thoroughly already. The easiest way of getting the bewildered look off their faces is to tell them that no doctor in his senses *likes* to work with a crowd of aggrieved and apprehensive patients waiting on the far side of the door.

* * *

The communal bathrooms of our residents' quarters provide unrivalled opportunity for the study of shaving habits. Our Welsh Wizard, always the last to arrive, hurries in completely dressed except for his jacket, with his left hand in his trouser pocket and a cigarette dangling from his mouth. He shaves still with cigarette in mouth and ash dropping into the basin, still with hand in trouser pocket, generously splashing soap-suds over his shirt front. The shaving itself takes little time but is followed by an amazing performance. Many dry and strop their razor blade after use on the palm of their hand, but our friend protrudes his abdomen and dangerously sweeps the blade up and down the upper part of the fly of his trousers. I have suggested that he has a piece of leather sewn in this situation but he ignores my advice. He struts out of the bathroom leaving the door wide open regardless of nudity prancing about.

How different is the technique of our slow and highly conscientious surgeon, who takes at least half an hour to shave. Each hair receives individual attention, each small area is carefully shaved again and again, carefully massaged with finger-tips, lovingly stroked, and then relathered. Knowing him as I do, I would have predicted such a palaver even if I had never seen him shave.

Our anæsthetist adopts a totally different policy. He wets a face-flannel and slowly and laboriously wipes it over his face, gazing at himself in the mirror. This is repeated many times for at least five minutes, with a careful inspection of his image between each smearing. Then he massages one of those brushless creams tenderly into his bristly jowls for a long time without any apparent effect. The rest of the business proceeds at the same slow pace with frequent resort to the face-flannel between the periods of razor-scratching. When at last the operation is over our dope doctor still looks as if he needs a shave.

Most of us have never been taught how to shave and these personal conceits of style, these individual habits associated with shaving, are, I submit, a guide to character and personality worthy of the psychologist's attention.

It is useful in terminating pregnancy where inhalation anæsthesia is inadvisable: the evacuated uterus contracts remarkably quickly. Though only a small specialised weapon, it has its place.

Dr. A. R. Hunter felt that the results of sympathectomy for hypertension are such as to make it doubtful whether they are worth evaluating. Epidural cellulitis, he said, can be as dangerous as meningitis. Dr. Gray spoke of collapse, with sudden fall of blood-pressure, when the block goes too high. Such collapse Dr. Steel attributed to persisting with the caudal block after getting a "bloody tap."

Intubation in Childhood

Dr. Robert Cope explained that in infants the laryngeal aperture is tiny, and an intratracheal tube must be introduced slowly. He reviewed the various stages of early life at which this may be necessary, from the relief of asphyxia neonatorum onwards. In the first few days, when operating on some major abnormality, a perfect airway may make all the difference. In the operations of the first few weeks—for pyloric stenosis, duodenal atresia, or intussusception—a tube allows anæsthesia to be lightened without laryngeal spasm.

Analgesia in Midwifery was discussed jointly with the section of obstetrics and gynæcology (see below).

OBSTETRICS AND GYNÆCOLOGY

President: Mr. J. R. Campbell-Canney

Infertility

To prevent the great unhappiness caused to so many couples by sterility Dr. Bethel Solomons advocated premarital tests. His opening paper covered the whole subject of infertility, but two facts in particular emerged—firstly, that he puts male responsibility as high as 50%, and secondly that deaths *do* occur from insufflation of the fallopian tubes. The danger of gas embolism is greatest with oxygen and air, but he has seen a death during insufflation with carbon dioxide. It is a duty, he said, to publish fatal cases of this kind. Mr. Albert Sharman held that for uterotubal insufflation only carbon dioxide should be used: he advised that insufflation should take place in the premenstrual phase, when a premenstrual biopsy can be performed after it.

Mr. Kenneth Walker's main theme was the importance of complete examination of semen specimens; but he also dwelt on the abnormalities associated with ejaculation and mentioned the possibility of retrograde ejaculation into the bladder, as occurs after prostatectomy. He made a plea for the wider use by gynæcologists of the post-coital test, which is, after all, the final test of the man's ability to impregnate his wife.

Mr. Percy Malpas dealt with the difficult subject of recurrent abortion. He thinks that perhaps we have over-emphasised the hormonal factor. Apart from cases where a well-defined organic basis can be found, such as renal disease or some local abnormality, he contended that abnormalities of the nervous system, affecting uterine quiescence, are mainly responsible for habitual abortion in the first few months of pregnancy. If a sustained nervous inhibition *is the means by which the pregnant* uterus is normally kept quiescent, rest should be the main therapeutic agent in these cases.

Mr. Cecil Binney, a barrister-at-law, brought his expert legal mind to bear on the subject of artificial insemination. He argued that artificial insemination with donated semen cannot be used as grounds for divorce, since it cannot be interpreted as an act of adultery. (Adultery is a sexual act, which has nothing to do with the conception of a child, and birth of a child without a sexual act can hardly be adultery.) Nor can artificial insemination be used as grounds for divorce in relation to nullity. On the other hand donor insemination introduces almost insuperable difficulties in conne with the law of inheritance of settled funds. In subsequent lively discussion on this, as on other aspects of insemination, the general view seemed to be that the practice should be left to somebody else.

The frequency with which pregnancy follows adoption of a child led to the suggestion that babies might be borrowed for the specific purpose of relaxing tension and stimulating mother-love. Fanciful though this may be, the meeting was left with the feeling that there are more things in heaven and earth than are dreamt of in our philosophy; members were reminded that in assessing results in the cure of infertility they must be humble, because nature herself so often cures without human aid.

Analgesia in Midwifery

Prof. W. C. Nixon opened the second discussion with an inspiring paper which went far beyond the consideration of particular analgesics or anæsthetics. He pointed out that the more complete the antenatal preparation of the patient, the more physiological her labour will be and the less pain she will have. The relief of pain in the labour ward should begin in the antenatal clinic. Confidence thus inspired in the patient goes a long way towards removing fear and inhibitions that ultimately impede the natural processes of childbirth. Professor Nixon spoke also of the need for sleep during labour, especially at the natural time for sleeping at night, and discussed the various drugs that might be used to promote it. He discouraged the use of barbiturates, but from further experience at University College Hospital he advised the use of pethidine in doses of 150 mg. At this hospital investigations are being carried out by a full-time research anæsthetist appointed to the obstetric department, and this is a development in hospital organisation that other units should pursue. Only if obstetricians and anæsthetists work together can satisfactory team-work be attained and the pati be legitimately relieved of unnecessary pain.

The next speakers were Dr. P. J. Helliwell and Dr. A. M. Hutton, both of whom are working with a research grant at Guy's Hospital. Reporting at some length on their investigations with 'Trilene' in midwifery they concluded that the danger of the self-administered trilene inhalers is by no means negligible, and that the patient should never be left alone with a self-administered trilene inhaler. The value of trilene in midwifery is nevertheless very considerable, and the general view is that it is the most useful supplement for gas-and-oxygen or gas-and-air. During the discussion chloroform received many bouquets from experienced and older practitioners, and caudal analgesia was mentioned as very valuable in carefully selected cases and in experienced hands.

The Third Stage and its Complications

The third stage of labour appropriately occupied the final stage of the section's meetings.

Mr. J. D. S. Flew put in a strong plea for the use of oxytocic drugs—ergometrine in particular—before the delivery of the placenta in cases of hæmorrhage. Considerable changes are nowadays being made in *management of the third stage*, both normal abnormal. In particular the older teaching of Cr expression and bimanual compression is now recognised as often dangerous and productive of shock. This a vitally important point, because midwives up and down the country are still being taught manual removal the conscious patient—a method which they would never carry out in practice—as well as Credé expression. Far less harm would be done if they were allowed to give an oxytocic drug to control immediate hæmorrhage. Later speakers all agreed with Mr. Flew in condemn the old-fashioned methods of expressing the placenta which can often far more safely be expressed from the

Five patients have completed 4-month courses, and umber of others courses of up to 4–5 weeks. In each the five cases which have received 4-month courses amount given was 12–14 g. daily, in seven doses ourly with one interval of 6 hours at night. In all them further progress of the disease has been checked, ough complete cure can be claimed in none. With e exception (case 4) the patients had the rapidly ogressive, exudative form of the disease. They were verely toxic, with swinging temperature, high blood-dimentation rate, and sputum loaded with tubercle cilli; and monthly radiological examination had vealed continuing spread despite absolute bed rest and other therapeutic measures except streptomycin.

The considerable improvement in general condition, creased appetite, gain in weight, and loss of toxicity ve been well maintained in all these cases, 4 weeks after e completion of the course. The temperature has also mained normal, except in case 2 where the curve tended creep up after completion of the first 8-week course; ere a pause of 4 weeks had to be interposed owing to pply difficulties, and the second 8-week course did t completely suppress the pyrexia. But even in this se the improvement in general condition and X-ray ppearances has been maintained. In the other cases the -ray appearances present a picture as hopeful as the inical aspect. In all, progress of the disease has been hecked; the soft mottling has disappeared, and there pronounced hardening of the major lesions with ore-or-less definite fibrosis.

No true sputum conversion could be demonstrated any of these cases, though the bacilli have become ery scanty and have commonly been absent from the eekly specimens for 6–8 weeks. The strain cultured ith *p*-aminobenzoic acid added shows no increased ensitivity for P.A.S. against the HR 37; this conforms ith Davis's[2] observations.

Regarding laboratory findings, blood P.A.S. levels of –8 mg. per 100 ml. have been uniformly reached after g., and up to 11 mg. per 100 ml. has been reached fter 3 g.; the blood-level sinks rapidly below 3 mg. er 100 ml. after 3 hours. The urinary concentration also fairly constant at 45–50 mg. per 100 ml. It is stimated that about half the P.A.S. is excreted as such the urine, from which the drug disappears within 0 hours of discontinuing intake. The concentration the sputum varies from 1 to 5 mg. per 100 ml.; a igher concentration is apparently present in purulent an in mucous sputum.

No real toxic manifestations have been observed at aily doses of up to 25 g.; but in a few instances nausea nd even vomiting have set in, perhaps because the olution was given without sufficient dilution, or because was not suitably flavoured. With attention to these oints, the symptoms have always disappeared. Even mall doses of aspirin inadvertently given may, however, recipitate symptoms of severe salicylate poisoning.

In all cases where P.A.S. has been tried the picture as followed the same pattern—loss of toxicity, control f pyrexia and cough, increased appetite, and gain in eight. Some of the patients are now fit for surgical eatment. The remainder, unsuitable for surgery, will oon present the problem of what is to be done with them. Vill they get along as inactive open cases, or will further ourses of P.A.S. be needed to ensure a reasonable span f life? I feel that in earlier cases, with less gross estruction of the lung, P.A.S. may well afford a complete ure. It also seems that the daily dose must be greatly creased—to not less than 20–25 g.—and must be ontinued for at least 3 months if better results are to e achieved. Local treatment with 1–2% spray should so be included. Probably a P.A.S. "umbrella" will duce the risk of spread or reactivation through operaon or during pregnancy. It thus seems that P.A.S. ay be regarded as the beginning of an answer to the roblem of tuberculosis; but new and more promising ompounds are already emerging from the laboratories.

I am grateful to Dr. W. E. Snell for facilities at Colindale ospital, and to Dr. George Day and Dr. E. C. Wynne-dwards for similar courtesy at Mundesley Sanatorium. am also indebted to Messrs. Ward, Blenkinsop & Co. Ltd., r free supplies of P.A.S.

London, S.W. A. ERDEI.

NATIONAL SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE

SIR,—The latest report of the Ministry of Health has to acknowledge an alarming setback in venereal disease that has dismayed everyone who understands its significance. The report says: "During the year 1945 the incidence of syphilis and gonorrhœa increased appreciably."

This has happened after large sums of public money have been spent by the Government, through the Central Council for Health Education, in telling the public of the dangers of V.D., and in trying to conquer V.D. by fear and persuasion, coupled with treatment after the disease has developed. The public has not been allowed to learn the vitally important fact that a great deal of V.D. is easily prevented. This is a scientific fact and it has been known for 40 years.

During the great wars the fighting Services all over the world, owing mainly to the persistent efforts of this society, were protected (more or less, according to the enthusiasm of the officer-in-charge) against these diseases by the preventive measures we have advocated for thirty years. But the civilian population all the time has been kept in ignorance, and so V.D. is on the increase.

The statement by the Government-appointed Trevethin Committee (1922) that "properly and promptly applied disinfection . . . would almost certainly prove effectual" has been ignored, and up to the present no Government has had the courage to translate these findings into action. It has been left to us, a voluntarily supported society, to work alone. And we have to fight not only disease, but very often violent prejudice as well.

Our policy is threefold: (1) to educate the public with regard to the fact that V.D. can be prevented by simple, scientific measures; (2) to supply all interested persons with details of such measures; and (3) to secure the necessary alteration of the law to enable the preventive materials to be sold together with the necessary instructions. This society cordially supports any and every method whereby V.D. may be combated, but it is confident that V.D. will be eliminated only by practical prevention. Without practical prevention any campaign against V.D. is doomed to failure.

About 100,000 men and women sufferers from V.D. will be treated at clinics this year, and there will be a great number of infected persons who will not go to clinics.

We are planning a great campaign to set the people free from V.D. and from the prejudiced tyranny that has kept them in ignorance of the facts. The scope and magnitude of this great attack depends upon the support we receive from the profession and from the general public. Let us show you how you can help.

CONTROL IN SCHICK-TESTING

SIR,—Last year you published some of my original findings on the properties of Holt's diphtheria toxoid (P.T.A.P.).[1] Since then I have encountered an unexpected difficulty, which I feel ought to be communicated to other workers.

For many years it has been assumed that infants and children under five years of age very rarely indeed become sensitive to the protein substances present in diphtheria prophylactics. It was believed, and rightly so, that if a control injection were used in post-Schick tests in infants, it practically never revealed any acquired protein sensitivity. Consequently it was considered quite sound practice to dispense with the control injection in infants and very young children, reserving it for use in the over-fives.

In the course of investigating various experimental samples of Holt's P.T.A.P., I recently became disturbed at the number of faintly positive post-Schick readings I was obtaining in very young children. The number was not large but was beyond my expectations, and I became suspicious. From that moment I readopted the use of the control injection and found that most of the cases that I had been obliged to regard as feebly positive were, in fact, pseudo and negative. The

1. *Lancet*, 1947, i, 280; *Ibid*, ii, 867.

During the past couple of years I have attended many memorial lectures at the Royal Colleges. To say that I can recall very few that have been worth hearing is to intend no reflection on the ability of the lecturers or the quality of their material.

I realise that these lectures fulfil a purpose, if only to express the colleges' appreciation of the status and reputation of their selections. Moreover, there is often a desire on the part of those attending to indicate a personal regard for a lecturer, who will interpret one's attendance as a compliment. But excluding sentiment and considering the essentially practical point of view, I have usually found it sheer waste of time.

In nearly all instances page after page of manuscript is read out, often inaudibly, generally monotonously, and almost invariably too rapidly in an obvious anxiety to cover the whole of the ground in the allotted time. All that results is a blurred sensation with occasional perception of technical details, and I believe most of the audience hypnotise themselves into a state of self-deception although hearing little and understanding less.

It seems to me that the lecturer should prepare a special sort of abstract, summary, abridgment, synopsis, or whatever is the proper description, which could really *be delivered as a lecture to give a readily* comprehended impression, and that he should not attempt anything more elaborate. The address in its entirety would then appear in one of the journals where it could be studied with the care essential for proper understanding.

I do not anticipate an enthusiastic reception of this idea, but from my considerable experience as a lecturee I feel sure I am right.

* * *

It may hearten you in England to know that we in Indiana, U.S.A., think of you more often than either of us realise. The other morning (2 A.M.) I telephoned the telegraph office. In giving my message, for sake of clarity I pronounced "laboratory" as you do, instead of as we do with the emphasis on the "lab" and the rest slithering away back into the nasopharynx. To my delight the elderly male voice at the other end of the line remarked, "That's the English way, isn't it, sir? That's how Sherlock Holmes pronounced it."

* * *

A few days ago with some fellow enthusiasts I attended a numismatic conference in a neighbouring town. Before the meeting we visited the local museum which houses a very fine collection of coins. There we were kindly received by the curator of that section, whom we found busy making plaster casts. This is done because the casts photograph better than the original coins for the purpose of an illustrated catalogue. The coin is first pressed into modelling wax; then it is removed and plaster-of-paris is poured into the cavity and allowed to set. This gives a perfect plaster cast of the coin.

In the process the wax has to be firmly moulded round the coin, largely by pressure of the lateral side of the terminal phalanx of the left thumb. The curator has made so many thousands of these casts that, as he pointed out, the terminal phalanx of his thumb has become permanently and obviously deformed, being displaced laterally some 10–15° and slightly flattened. This seems to be a new occupational disease, which I have tentatively named "numismatist's thumb," thus forming a triad with the better known "miner's elbow" and "weaver's bottom." It is possible that a long and minute account of it exists in some tome as *Numismatischekuratorskrankheit* (von Kraschundbang's disease), but until that is proved I propose to put forward the discovery as my sole claim to fame.

* * *

It is all very well to say that if one is to keep satisfactory records one must have a good nosological index, but where would you put this case? A large navvy complained of pain in both feet for two months. His panel doctor was uncertain of the diagnosis, so he referred him to hospital. Careful questioning revealed that the patient had bought a smaller pair of boots than usual at the time of onset. The dawn of understanding as the patient realised the cause of his pains was worth seeing. But what is the diagnosis?

Letters to the Editor

REPRESENTATION OF SPECIALISTS

SIR,—But for the promise of an Amending Act the present state of the profession would be chaotic: as it is, we wait anxiously to see the effect on general practitioners of the terms which many of them have accepted. Some of us feel that a better service could have been obtained by a wiser policy and better negotiators. To consultants feeling so, the British Medical Association's new plan for organising us does not come with good testimonials, and examination increases uneasiness.

Satisfactory representation for general practitioners should have been easily obtained: they are relatively evenly dispersed, their work is uniform in character, and all that is needed is geographical division. But representation of specialists and consultants is very different. These gather essentially in centres with high standards; the wisdom of a few men of world-wide repute in teaching hospitals can outweigh that of many elsewhere. Moreover, not only are they thus irregularly dispersed, but they are not interchangeable as are the general practitioners; a surgeon cannot change suddenly to psychiatry or a physician to otorhinolaryngology. The problem of representation is so different that the machinery cannot be the same. For this reason the original B.M.A. plan seemed far from being in the best interests of the profession, especially if non-teaching hospitals could outvote the teaching hospitals by as much as 9 to 1. Although such criticism was at first termed an abandonment of democracy, the B.M.A. itself hastened to recommend that the representation of the two types of hospital in a region should be equalised, and each region send to a central committee 1 member from the teaching and 1 from the non-teaching hospitals.

This does indeed abandon democracy, but only if democracy means making the interest of the individual consultant more important than the interest of his specialty. It leads, more seriously, to an arrangement by which regions will send to a central committee an entirely fortuitous collection of physicians, surgeons, and obstetricians and gynæcologists. There are no means by which this central committee can provide for itself the very necessary correct proportion of representatives of the three supremely important branches of medicine which every physician, surgeon, or gynæcologist would wish to see. This is not an academic question: the method of committee formation suggested by the B.M.A. has been tried in at least one hospital region and found unsatisfactory, and representation must be by specialties properly balanced if committees are to do their work as it needs to be done. When this balance is a matter of chance, and when the committee itself has as many as 72 members, the usefulness of the scheme is very doubtful indeed and its value for negotiation appears negligible, if it is not actually harmful. Indeed non-teaching consultants have already been well treated; they are recognised by the Spens report and the Minister as the financial equals of their metropolitan colleagues. But this does not make them equal in other ways. Such recognition should be regarded as a trust, which they must fulfil that in time they will make their individual and institutional work equal too. The opportunity was won for them very largely indeed through the efforts of college representatives. Would it not be wise for them to return the trust, and believe that through the colleges they will find representatives who will obtain for them *other advantages such as those they already owe*—the Amending Act and the Spens report?

Hove, Sussex. **W. A. BOURNE.**

p-AMINOSALICYLIC ACID IN TUBERCULOSIS

SIR,—Since the publication of my first report[1] on the systemic treatment of pulmonary tuberculosis with *p*-aminosalicylic acid (P.A.S.), commercial production of the drug has started; and though still very scarce it is now available for clinical work. It may therefore be useful to summarise the experience gained in the first six months of trial and error.

---

[1] *Lancet*, 1948, i, 791.

ive patients have completed 4-month courses, and umber of others courses of up to 4–5 weeks. In each the five cases which have received 4-month courses amount given was 12–14 g. daily, in seven doses ourly with one interval of 6 hours at night. In all them further progress of the disease has been checked, ough complete cure can be claimed in none. With exception (case 4) the patients had the rapidly ogressive. exudative form of the disease. They were erely toxic, with swinging temperature, high blood-limentation rate. and sputum loaded with tubercle cilli; and monthly radiological examination had ealed continuing spread despite absolute bed rest and other therapeutic measures except streptomycin.

The considerable improvement in general condition, creased appetite, gain in weight, and loss of toxicity ve been well maintained in all these cases. 4 weeks after e completion of the course. The temperature has also mained normal. except in case 2 where the curve tended creep up after completion of the first 8-week course; re a pause of 4 weeks had to be interposed owing to pply difficulties, and the second 8-week course did t completely suppress the pyrexia. But even in this se the improvement in general condition and X-ray pearances has been maintained. In the other cases the -ray appearances present a picture as hopeful as the inical aspect. In all, progress of the disease has been ecked: the soft mottling has disappeared, and there pronounced hardening of the major lesions with ore-or-less definite fibrosis.

No true sputum conversion could be demonstrated any of these cases, though the bacilli have become ery scanty and have commonly been absent from the eekly specimens for 6–8 weeks. The strain cultured ith *p*-aminobenzoic acid added shows no increased ensitivity for P.A.S. against the HR 37; this conforms ith Davis's[2] observations.

Regarding laboratory findings, blood P.A.S. levels of –8 mg. per 100 ml. have been uniformly reached after g., and up to 11 mg. per 100 ml. has been reached fter 3 g.; the blood-level sinks rapidly below 3 mg. er 100 ml. after 3 hours. The urinary concentration also fairly constant at 45–50 mg. per 100 ml. It is stimated that about half the P.A.S. is excreted as such the urine. from which the drug disappears within hours of discontinuing intake. The concentration the sputum varies from 1 to 5 mg. per 100 ml.; a igher concentration is apparently present in purulent an in mucous sputum.

No real toxic manifestations have been observed at aily doses of up to 25 g.; but in a few instances nausea nd even vomiting have set in. perhaps because the olution was given without sufficient dilution, or because was not suitably flavoured. With attention to these oints, the symptoms have always disappeared. Even mall doses of aspirin inadvertently given may, however, recipitate symptoms of severe salicylate poisoning.

In all cases where P.A.S. has been tried the picture as followed the same pattern—loss of toxicity, control f pyrexia and cough. increased appetite, and gain in eight. Some of the patients are now fit for surgical eatment. The remainder, unsuitable for surgery, will on present the problem of what is to be done with them. ill they get along as inactive open cases, or will further ourses of P.A.S. be needed to ensure a reasonable span f life? I feel that in earlier cases, with less gross estruction of the lung, P.A.S. may well afford a complete re. It also seems that the daily dose must be greatly creased—to not less than 20–25 g.—and must be ontinued for at least 3 months if better results are to e achieved. Local treatment with 1–2% spray should lso be included. Probably a P.A.S. "umbrella" will duce the risk of spread or reactivation through opera- on or during pregnancy. It thus seems that P.A.S. ay be regarded as the beginning of an answer to the roblem of tuberculosis; but new and more promising ompounds are already emerging from the laboratories.

NATIONAL SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE

SIR,—The latest report of the Ministry of Health has to acknowledge an alarming setback in venereal disease that has dismayed everyone who understands its significance. The report says: "During the year 1945 the incidence of syphilis and gonorrhœa increased appreciably."

This has happened after large sums of public money have been spent by the Government through the Central Council for Health Education, in telling the public of the dangers of V.D., and in trying to conquer V.D. by fear and persuasion, coupled with treatment after the disease has developed. The public has not been allowed to learn the vitally important fact that a great deal of V.D. is easily prevented. This is a scientific fact and it has been known for 40 years.

During the great wars the fighting Services all over the world, owing mainly to the persistent efforts of this society, were protected (more or less, according to the enthusiasm of the officer-in-charge) against these diseases by the preventive measures we have advocated for thirty years. But the civilian population all the time has been kept in ignorance, and so V.D. is on the increase.

The statement by the Government-appointed Trevethin Committee (1922) that "properly and promptly applied disinfection . . . would almost certainly prove effectual" has been ignored, and up to the present no Government has had the courage to translate these findings into action. It has been left to us, a voluntarily supported society, to work alone. And we have to fight not only disease, but very often violent prejudice as well.

Our policy is threefold: (1) to educate the public with regard to the fact that V.D. can be prevented by simple, scientific measures; (2) to supply all interested persons with details of such measures; and (3) to secure the necessary alteration of the law to enable the preventive materials to be sold together with the necessary instructions. This society cordially supports any and every method whereby V.D. may be combated, but it is confident that V.D. will be eliminated only by practical prevention. Without practical prevention any campaign against V.D. is doomed to failure.

About 100,000 men and women sufferers from V.D. will be treated at clinics this year, and there will be a great number of infected persons who will not go to clinics.

We are planning a great campaign to set the people free from V.D. and from the prejudiced tyranny that has kept them in ignorance of the facts. The scope and magnitude of this great attack depends upon the support we receive from the profession and from the general public. Let us show you how you can help.

HORDER
President, National Society
for the Prevention of Venereal Disease.

CONTROL IN SCHICK-TESTING

SIR,—Last year you published some of my original findings on the properties of Holt's diphtheria toxoid (P.T.A.P.).[1] Since then I have encountered an unexpected difficulty, which I feel ought to be communicated to other workers.

For many years it has been assumed that infants and children under five years of age very rarely indeed become sensitive to the protein substances present in diphtheria prophylactics. It was believed, and rightly so, that if a control injection were used in post-Schick tests in infants, it practically never revealed any acquired protein sensitivity. Consequently it was considered quite sound practice to dispense with the control injection in infants and very young children, reserving it for use in the over-fives.

In the course of investigating various experimental samples of Holt's P.T.A.P., I recently became disturbed at the number of faintly positive post-Schick readings I was obtaining in very young children. The number was not large but was beyond my expectations, and I became suspicious. From that moment I readopted the use of the control injection and found that most of the cases that I had been obliged to regard as feebly positive were, in fact, pseudo and negative. The

---

1. *Lancet*, 1947, i, 286; *Ibid*, ii, 867.

danger is that these readings, which proved to be so tricky without the use of control, were not like typical fading pseudo-reactions; they were too circumscribed and their colour was too uniformly even. Yet against the control solution they proved to be pseudo-reactions.

It is somewhat humiliating, after all these years, to realise that one can be caught napping by a quite atypical form of pseudo and negative reaction; but my experience may serve as a warning to others.

I do not think that the value of my comparative experiments (already published) is likely to be in any way invalidated, as the pseudo error (not large) is applicable to all the groups which were under consideration. But for those desirous of finding out whether the powerful modern prophylactics are yielding a 95% or a 99% conversion-rate, I cannot too strongly emphasise the necessity of using the control in all post-Schick tests.

I have, as always, used the Wellcome brand of toxin and control in this investigation.

London, S.E.5. GUY BOUSFIELD.

HEXOBARBITONE AND TUBARINE

SIR,—An excessive amount of abdominal pain has been experienced by some patients when first regaining consciousness after an abdominal operation under light anæsthesia and relaxation with 'Tubarine.' I attributed this to:

1. Early restoration of consciousness and body function *per se* as compared with other methods of anæsthesia, allowing immediate postoperative abdominal discomfort to be experienced at all.
2. The variable, but, I think, often excessive contraction of the gut following administration of tubarine. Gray and Halton[1] comment on this and also show clearly the synergism that exists between curariform drugs and barbiturates.

It occurred to me, therefore, to try going back to the use of hexobarbitone because of its more prolonged action, and particularly because of its pleasant postoperative effect of sustaining a light sleep for some hours. This change has been justified by results. Relaxation during operation has been prolonged and sustained up to one hour and less cyclopropane has been required; but the chief benefit has been the postoperative comfort of the patient, who, having experienced much less pain, gets a pleasant sleep until the effects of the operation have worn off. I also think there is less intestinal contraction. HUGH D. BROWNE.

Memorial Hospital, Haywards Heath.

APPARENT ACUTE GLOMERULONEPHRITIS WITHOUT ALBUMINURIA

SIR,—The syndrome described last week by Dr. Crofton and Dr. Truelove vividly recalls to my memory experiences which during the first world war were puzzling many clinicians in Central Europe.

Many victims of the so-called *Kriegsnephritis* had died of acute œdema of the lungs before admission to hospital because, in view of the absence of albuminuria, the combination of generalised œdema and bradycardia had led the doctors on the front to the erroneous diagnosis of *Kriegsœdema*. Unfortunately the leading symptom of severe dyspnœa was overlooked. I saw many cases of analbuminuric acute glomerulonephritis at Wenckebach's First University Clinic in Vienna during 1917 and 1918. Apart from albuminuria they presented the full picture of acute glomerulonephritis—i.e., severe hypertension, œdema, and bradycardia. The skin capillaries revealed dermatoscopically the characteristic picture which I described in 1920.[2] The most striking sign, however, was acute or subacute œdema of the lungs, which was invariably present and was demonstrated by the cloudy appearance of the lung fields on screening. Under the then-prevalent Volhard's "fast-and-thirst" régime the majority of cases recovered, albuminuria appearing on the third or fourth day. Necropsy of patients who had died of acute left ventricular failure showed typical acute glomerulitis with all histological details.

The syndrome should preferably be termed "analbuminuric stage of acute diffuse glomerulonephritis" since albuminuria eventually appears after a few unless the patient succumbs to acute œdema of lungs. It may be added that routine blood-p readings in patients with scarlatina often reveal a in blood-pressure before albuminuria attracts atten to the kidneys—a point of great interest in pathogenesis of acute diffuse glomerulonephritis

A TAX ON KNOWLEDGE

SIR,—Is there not an analogy with the legal profe as regards the use of books by doctors (referred to in your leading article last week)? The position in re of income-tax is controlled by a decision by Mr. Justi Rowlatt (Daphne *v.* Shaw [1926] 43 T.L.R. 45) in whic he "was unable to say that the books of a solicitor o of a barrister or of a judge which were used in the se of being consulted were plant." Discussing this poi the *Solicitor* (September, 1947, p. 195) observed:

> "That bases the decision, as it must be based, upon the actual words of the statute, which are really inapplicable t the occupation of a solicitor. Apparently some inspector of taxes have taken a more practical view of the pres conditions and have allowed members of the Bar an allowan for their books. Writers, too, receive an allowance for book purchased to meet the requirements of their work."

It seemed to the *Solicitor*, however, as if in the long ru an amendment of the law may be necessary, and attentio was drawn to the Australian Income-Tax Acts in which an allowance for libraries has definite recognition.

C. E. A. B.

POSTURE AND PRESSURE

SIR,—Your annotation of June 26 states that more than fifty years ago I demonstrated that four-legged animals would die from cerebral anæmia if kept upright for a few days. This is not correct. What I found wa that big-bellied hutch rabbits when suspended, stretched out, in the vertical, head-up position quickly fainted from the blood sinking into the abdomen, and were a once restored by a bandage drawn round this. Th bellied wild rabbits did not faint. I also showed International Physiological Congress at the Cambri meeting, held so long ago, that when a snake was fixed a board, drawn out full length, and put in the vert position the blood ceased to fill the heart, standing the veins just below it. On sinking the board and anim in a tall cylinder of water the heart filled, the pres of water outside balancing that of the blood in th animal.

Smallfield, Surrey. LEONARD HILL

SIR,—Hill[1] did not show that the upright positi would kill four-legged animals in "a few days," h referred to Solathé[2] who found that in the vertical fe down position rabbits died in the course of 15 minutes 2 hours.

The effect of change of posture on the blood-pressure has been investigated many times. The largest se of controlled observations is that of Schneider and Truesdell,[3] who reported results in 2000 normal adults They found that there was a wide variation in the indi vidual response. The pulse change on standing varie from a slowing by 15 beats per min. to an increase o 57 beats. In over 84% of cases, there was an increa of up to 30 beats. When the results were plotted a histogram, a typical frequency distribution cu resulted. A similar variation was noted in the chan in blood-pressure. This variation is what would expected of biological observations and was recorde Hill and Barnard[4] in dogs. The changes are neces for two reasons: (1) the fall in cardiac output t takes place in the upright position, and (2) the cha in the relative positions of the heart and the In the erect position energy has to be expended to the blood from the level of the heart to that of the br The adjustment is a nervous one mediated by the caro sinus mechanism, and if both carotid sinuses in m are denervated the mechanism fails and postu hypotension results.[5]

---

[1] Hill, L. *J. Physiol.* 1895, 18, 15.

[2] Solathé (1877) quoted by Hill.

[3] Schneider, E. C., Truesdell, D. *Amer. J. Physiol.* 1922, 61, 4

[4] Hill, L., Barnard, H. *J. Physiol.* 1897, 21, 324.

[5] Capps, R. B., de Takats, G. *J. clin. Invest.* 1938, 17, 385.

t has been shown by Pickering, Kissin, and Roth- ild[6] that in human hypertension the carotid sinus ctions normally, and that the hypertension differs m that produced experimentally by denervating the otid sinuses and aorta. It is therefore unlikely that ervations on the effects of a nervous reflex concerned h compensation for postural change would provide guide to the chances of an individual developing pertension.

To regard a rise of 4 mm. Hg in the diastolic pressure significant is arbitrary and unjustified. Schneider and uesdell found the average rise in diastolic pressure standing in their series of 2000 normal adults to be mm. Hg.

D. VÉREL.

Department of Medicine, University of Aberdeen.

PILONIDAL SINUS IN A BARBER'S HAND

SIR,—I should like to record a case similar to those scribed by Ewing[7] and by Patey and Scarff.[8]

In 1941 a barber presented himself with an abscess in e web between the middle and ring fingers of his left hand. maintained that this was due to penetration by the ort cut hairs, and that this was the third time a suppurative ocess had developed at that site. On incision pus and umerous short hair clippings discharged.

This patient was in the habit of running his fingers rough his clients' hair and supporting it thus while ing the scissors. It was during this procedure that the ir clippings reached the web.

Edinburgh.

GODFREY B. TAIT.

SIR,—Some time ago I saw what must have been a milar case to those described by Mr. Patey and rofessor Scarff.

I was having my hair cut, and in the course of conversation e barber mentioned that he was having trouble with hair netrating the web of his fingers. Asking if I would like have a look, he stripped off some plaster and proffered s hand for inspection. There, between the thumb and refinger of his cutting hand, was a little tuft of hair pro- uding from the web. The longest of the hairs penetrated raight in to a depth of about $^1/_4$ in. There was no sign inflammation round the tiny hole in the skin; nor was ere any induration along the track of the hairs. This d towards a swelling deep in the web which was the size a small pea, cystic and painless; I assumed it was an plantation dermoid.

The barber, telling me his doctor was going to " open ," resumed his cutting while I pondered on how the ir got in.

London, W.11.

J. M. WILKS.

SIR,—Patey and Scarff have drawn attention to an teresting occupational condition. I met with a milar case in the casualty department of the Royal orthern Hospital in 1939.

The man, a barber by trade, presented with a discharging scess in the cleft between the ring and middle fingers of e left hand. Projecting from the discharging sinus were merous hairs, of all different colours and lengths. The ainage was improved by a surgical incision, and a great any more hairs were found on laying open a chronic abscess vity. As I had not met the condition before I questioned e patient, who informed me that it was a not uncommon ndition amongst his fellow-craftsmen. I instructed him look out for other such cases and refer them to me. fortunately no such patients reported.

e ætiology of such a condition is best explained in e simplest terms. The hairs in this case were all oderately short and fairly bristly, although differing ghtly in texture and widely in colour. The lesion s situated in the cleft where the barber constantly dged his comb while using the scissors with his right nd, and it would seem probable that this played some rt in driving the short stiff hairs into the soft skin of the web. The site of the lesion was the same in all cases recorded, with the exception of the first reported by Patey and Scarff (1946). In Ewing's case it was in the corresponding cleft of the right hand. It would be interesting to know whether this man was left-handed and lodged his comb in that cleft. An alternative explanation might be that pressure resulted from the way a barber palms his scissors, using the thumb and ring finger. Further evidence of the power of hair clippings to penetrate skin and cause infection is the common occurrence of acute and chronic paronychia with foreign hair found to be in lodgment—a condition which I have seen on numerous occasions.

There is little support for the suggestion made by the authors that herein lies an explanation of the hair found in a pilonidal cyst (postanal dermoid, anococcygeal cyst). Admittedly this condition is one commonly found in men, especially of the hirsute type. On the other hand, many people have congenital sinuses and cysts which do not contain hair, merely because they are not formed in that hairy type of person. Routine examination of the natal cleft of all types of persons reveals a surprisingly high incidence of minute pits in and about the midline over the coccygeal region. Many give a history of one or more transient attacks of pain and inflammation that have often resolved with conservative measures. There is a satisfactory embryological explanation of such lesions.[9] When hair is found in a sinus or lesion of this sort, it is always long and fine and tapering at the end, and not of a type that is likely to penetrate. The possibility of its being " sucked in," suggested by the authors, is difficult to accept.

St. Mary's Hospital, London, W.2.

C. PATRICK SAMES.

PAIN

SIR,—In his interesting article in your issue of July 3, Dr. Keele describes a case which, he considers, illustrates " the characteristic features of psychogenic pain." These he enumerates as: (1) irregularity of occurrence, with absence of evidence of organic disease; (2) response on several occasions to a placebo such as distilled water; and (3) irregular response to potent analgesics. But do these criteria provide sufficient foundation upon which to base such an important decision? Absence of evidence of organic disease actually affords no ground for regarding a pain as psychogenic, and diagnosis by subterfuge such as injection of distilled water is both outmoded and notoriously unreliable. Later in the article Dr. Keele himself writes that there has been a remarkable tendency to ignore the factor of suggestion in assessing many medical and surgical pain-relieving procedures, and with this I would heartily agree. Pains of organic origin not infrequently respond to suggestion, including injections of distilled water, more readily than so-called psychogenic pains, and this is sometimes a serious source of error.

Decision that a symptom is psychogenic is justified only on positive as well as negative grounds. Apart from absence of organic findings, there must be established some positive psychogenic basis. Further, the psychogenic factors must bear direct relation to the patient's symptoms for which the psychogenesis furnishes a purpose, however unconscious, irrational, and primitive. Thirdly, it is unwise to diagnose psychoneurosis in the absence of a history of previous neurotic trends. Additional evidence of psychogenesis may be afforded by an organically inexplicable mobility and ubiquity of the symptom. Variation in accordance with environmental circumstances that are likely to have an emotional, as distinct from a purely physical, influence may confirm. Finally, an early, progressive, and satisfactory response of the ailment to psychotherapy may clinch the diagnosis.

Must the distilled-water test be perpetuated as a diagnostic refuge for one more generation of housemen and students? A patient who complains, no matter how, as it may seem, exaggeratedly or unreasonably, of severe pain persisting or constantly recurring in the same site must be taken very seriously until the positive explanation of that pain is ascertained; and this even though his manner may suggest a wish to impress, perhaps to the point of deception, the severity of his pain on the

Unfortunately the experience of welfare officers indicates that, once the parties have found themselves at arm's length in the law-courts, the chance of reconciliation deteriorates.

Parliament

Medical Services in the Colonies

OPENING a debate on colonial affairs in the House of Commons on July 8, Mr. CREECH JONES, secretary of state for the colonies, said that during the past year there had been substantial developments in social policy. Universities were coming into being in the West Indies, in West Africa, and in Malaya, and the status of Makerere was being changed to that of a university college. Campaigns had been conducted with great success against pests and locusts in Africa; there had been campaigns against diseases of all kinds; the working unit in Gambia had been doing very good work in the field of nutrition. A panel had been set up for improving the medical services by the sending of consultants from this country to examine medical arrangements and work in conjunction with the medical services in Africa, and a vigorous housing and welfare policy had been pursued in the various territories. We were in these territories to guide them as quickly as circumstances permitted to responsible government within the Commonwealth, in conditions which ensured to the peoples fair standards of living and freedom from oppression from any quarter.

During the past year an endeavour had been made to secure a genuine measure of international coöperation in wide areas in regard to some of the problems of Colonial development. There had been a series of conferences with the French, Belgian, and Portuguese governments, which have given willing coöperation.

Dr. HADEN GUEST said that Africa was probably on the eve of a great increase in population such as happened in Britain about 150 years ago at the time of the Industrial Revolution. The director-general of medical services in Kenya had drawn attention to the fact that under existing circumstances the increased population could not be fed. He had said that unless changes were made we should be left with pestilence or war as remedies for over-population and starvation. Dr. Haden Guest suggested that these facts should be taken into consideration. He had seen in South Africa the complete demoralisation of African life created by industrial conditions. To a very large extent land in tropical Africa was still under some form of communal ownership. We ought to keep the majority of Africans on the land and improve their conditions and amenities while adding secondary industries.

Mr. A. M. SKEFFINGTON held that there were not enough European doctors and medical assistants. He hoped that ways would be found of extending medical training for Africans.

Replying to the debate Mr. D. R. REES-WILLIAMS, under-secretary of state for the colonies, said that the campaign against the tsetse fly was still only in the planning stage. A team in West Africa was trying out the effect of aircraft spraying. In addition the authorities were trying the old methods of bush clearance, research on the type of bush that the tsetse fed upon, and other approaches. There was a new drug called 7555, of which they were not as yet quite confident; it was still undergoing its field tests. Locusts, which were one of the age-old enemies of mankind, had been brought under control at some expense to the British taxpayer, and with international coöperation. A new serum was believed to render cattle immune to rinderpest.

QUESTION TIME

Professional Secrecy

IN the House of Lords Lord BALFOUR OF BURLEIGH asked H.M. Government to state precisely the nature of the difficulty in administering the venereal diseases Acts and regulations which had led to the withdrawal of the statutory protection of secrecy from persons receiving treatment at V.D. clinics, and to state whether it was contemplated that in future information as to attendance or non-attend V.D. clinics, or factual information as to the state of of persons receiving treatment, would in any circum be able to be communicated to the police by the officer of health or by a member of the V.D. services, and ask H.M. Government to state the number of cases in compulsory medical examination took place under Re 33B now repealed, and the number of cases (men and w separately) in which the persons examined were found to suffering from venereal disease.—Lord LISTOWEL repl The withdrawal of the provision simply results from revoking of the Public Health (Venereal Diseases) Regula of 1916. These regulations placed upon local autho the responsibility for the treatment of venereal diseases a have been revoked because this responsibility now devolv upon regional hospital boards under the National Hea Service Act. It no longer appears necessary to contin special statutory provision to the effect that treatment f venereal diseases shall be regarded as confidential. Th maintenance of secrecy does not primarily depend for its fo on any statutory provision but rather on the proper a normal relationship between doctor and patient. There i no reason whatever to apprehend that the confidential natu of venereal disease treatment will not continue to be as clos preserved as it always has been. The number of cases i which compulsory medical examination took place unde Regulation 33B was 13 men and 1116 women. Informati about how many of these were found to have venereal disea is not available.

In the House of Commons Sir ERNEST GRAHAM-LITTL asked the Secretary of State for Air whether he was aware that at a conference of A.O.C.'s held in November, 1947, at an R.A.F. unit in Germany attended by all doctors, padres, and commanding officers of the wing, M.O.'s were reminded that a long-standing regulation required them to divulge to the commanding officer the names and full medical details of patients under their professional care suffering from venere disease, these records being accessible to other persons th the C.O.; that, as these requirements constituted a brea of the obligation binding members of the medical profe not to divulge to third persons information received in th professional capacity, several medical officers present at t conference expressed reluctance to obey the regula and if he would consider its withdrawal.—Mr. A HENDERSON replied: The officers who attended this confere were reminded of a King's Regulation which requires a d sick return, showing the diagnosis and disposal of each c to be made to the commanding officer. I am aware t at the conference some misgivings were expressed a the regulation, which is, however, necessary to enable commanding officer to carry out his duties in regard to t health and welfare of his unit. The situation in the R.A is not analogous with that in civil life. A commanding offi is responsible for the health of his men and for reducing th risk of infection. He must therefore be made aware of ca of venereal disease in his unit. In the circumstances, I cann agree to the suggestion that this regulation should be withdrawn.

Suspension of Tuberculous Teachers

Mr. ANTHONY GREENWOOD asked the Minister of Educati (1) whether he had now reminded education authorities the standing instructions issued by the Ministry of He and his department that a teacher found to be suffering f active tuberculosis should be suspended from teaching (2) whether he had considered the desirability of mak compulsory for all teachers to have a regular medical ove in order to ensure that they were not carriers of tubercu and what decision he had reached.—Mr. G. TOMLINSON re I am sending my hon. friend a copy of a memorandum has been issued reminding education authorities of the to be taken when a teacher is found to be suffering from tuberculosis. The memorandum does not require teach be medically examined at regular intervals after their into teaching service.

Mr. GREENWOOD: Would my right hon. friend bear mind that it is extremely dangerous to rely on a med inspection which may have taken place 15, 20, or 25 y earlier, probably without the assistance of radiography, how does he propose to make his answer effective with regular medical inspections?

Mr. TOMLINSON: My hon friend will see from the me randum that I am suggesting that greater use might be ss radiography. But compulsion is a question, I think, would need to be very carefully considered.

SOMERVILLE HASTINGS: Could not more be done to rage teachers to have examinations by mass radiography five or ten years?

TOMLINSON: I think that question is raised in the randum.

RANKIN: Would my right hon. friend extend that idea ctors, nurses, milk attendants, and all other people who close contact with children?

further reply was given.

Dentists and the National Health Service

D. L. LIPSON asked the Minister of Health whether, in of the large number of dentists who had decided not e part in the General Dental Service under the National h Act, he would invite the Dental Consultative Com- e to meet him again in order to try and find agreement utstanding differences.—Mr. ANEURIN BEVAN replied: Sir. The terms of service offered to dentists are in my generous and reasonable and I believe that most indi- l dentists will feel the same.

. LIPSON: May I ask my right hon. friend whether, in of the happy result which followed the gesture to the ors, he will now make a similar gesture to the dentists, s to ensure that the benefits of the dental part of the th service reach the people at the earliest possible time?

r. BEVAN: I am convinced from the figures of the dentists ng up, that very soon almost all the dentists will be taking ice under the Act. In any case, we cannot submit to t may become, unless we are careful, blackmail.

Capitation Fee to Medical Practitioners

r HENRY MORRIS-JONES asked the Minister of Health the amount of the capitation fee to medical practitioners er the National Health Act would be arrived at; what actions came out of the 15*s*. 6*d*. per head; and how the unt for each area would be computed having regard to proportion of the population who had not selected a or.—Mr. BEVAN replied: Detailed arrangements are still er discussion with the British Medical Association.

r H. MORRIS-JONES: Is the right hon. gentleman aware a large number of general medical practitioners are very urbed about this; that there is grave fear that their l emoluments and income will be considerably reduced r pre-National Insurance income; and that they want now whether the total pool will be available to them?

r. BEVAN: I think they ought to await the results of discussions with the representatives of the medical fession.

tra Members of Regional Boards, Management Committees, and Group Hospital Boards

ir IAN FRASER asked the Minister of Health if Regional Group Hospital Boards had power to co-opt a limited nber of extra members.—Mr. BEVAN replied: No, Sir; Regional Hospital Boards, Hospital Management Com- tees and Boards of Governors of teaching hospitals e power to appoint committees and subcommittees sisting partly of outside members and to delegate functions hem.

ir I. FRASER: Is it not inevitable when these committees first set up that certain local interests, such as hospital rds and ex-Servicemen, and others, will be left out; would it not give great public satisfaction if there were, a 10 per cent margin for co-option? Mr. BEVAN: The l management committees and regional boards have power o-opt people on to the subcommittees, and also on to the se-committees of individual hospitals. I believe that will done on a very considerable scale.

Specimen Diets for Duodenal Sufferers

r. EDWARD EVANS asked the Minister of Food, whether would issue in addition to the specimen menus published he press, dishes suitable for sufferers from certain dis- ities such as duodenal ulcers in accordance with the ilability of supplies at the time.—Mr. JOHN STRACHEY lied: I have consulted the Minister of Health and we are prepared to do this, because sufferers from duodenal rs or similar troubles may need individual treatment and uld seek advice on diet from a doctor.

Diary of the Week

JULY 18 TO 24

Monday, 19th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
5 P.M. Prof. S. L. Baker: General Pathology of Bone.
6.15 P.M. Dr. C. H. Tonge: Surgical Anatomy in Regional Anæsthesia.

Tuesday, 20th

ROYAL COLLEGE OF SURGEONS
5 P.M. Professor Baker: General Pathology of Bone.
6.15 P.M. Dr. Tonge: Anatomy of the Oral Cavity.

Wednesday, 21st

ROYAL COLLEGE OF SURGEONS
5 P.M. Mr. E. B. Manley: Histology of Dental Tissues.
6.15 P.M. Prof. G. B. Wright: Spread of Infection in Tissues.
EDINBURGH POST-GRADUATE BOARD FOR MEDICINE
3.30 P.M. (Anatomy lecture theatre, University of Edinburgh.) Prof. H. Barcroft: Blood-flow through Extremities.

Thursday, 22nd

ROYAL COLLEGE OF SURGEONS
5 P.M. Prof. John Beattie: Changes in Volume and Distribution of Body Water under Conditions of Stress. (Bernhard Baron lecture.)
5 P.M. Prof. R. J. Brocklehurst: Taste.
6.15 P.M. Mr. Manley: Histology of Dental Tissues.

Friday, 23rd

ROYAL COLLEGE OF SURGEONS
5 P.M.: Mr. Manley: Histology of Dental Tissues.
6.15 P.M. Mr. R. T. Payne: Acute Infections of Salivary Glands.
BIOCHEMICAL SOCIETY
11.15 A.M. (Biochemistry Department, University of Glasgow.) Opening of two-day meeting.
EDINBURGH POST-GRADUATE BOARD FOR MEDICINE
4.30 P.M. Prof. G. F. Marrian, F.R.S.: Neutral 17-Ketosteroids.

Saturday, 24th

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, W.1
2.30 P.M. Dr. A. H. Harkness: Pathology of Gonorrhœa. (Presidential address.)
BIOCHEMICAL SOCIETY
11.15 A.M. Two-day meeting, continued.

Births, Marriages, and Deaths

BIRTHS

BATTEN.—On July 7, in London, the wife of Dr. Henry Batten—a son.

CANT.—On June 30, at Oxford, the wife of Dr. F. E. V. Cant—a daughter.

CHURCHILL-DAVIDSON.—On July 9, at Kuala Lumpur, the wife of Dr. H. C. Churchill-Davidson—a daughter.

DALE.—On July 5, the wife of Dr. Donald Dale—a son.

ELGOOD.—On July 9, at Cardiff, the wife of Dr. F. R. M. Elgood—a son.

JEANES.—On July 1, at Woolwich, the wife of Dr. C. W. L. Jeanes—a son.

JOHNS.—On July 3, at Banstead, Surrey, the wife of Dr. T. A. M. Johns—a daughter.

JOHNSON.—On July 4, in London, the wife of Mr. Harold Daintree Johnson, F.R.C.S.—a son.

MCDONALD.—On July 3, in Edinburgh, the wife of Surgeon Lieutenant R. S. McDonald, R.N.—a daughter.

MCLARDY.—On July 6, in London, the wife of Dr. Turner McLardy, M.B.E.—a son.

MARSH.—On July 1, the wife of Dr. Alan Marsh—a son.

MORGAN.—On July 7, the wife of Dr. G. O. Morgan—a daughter.

PENROSE.—On July 2, at Bristol, the wife of Mr. J. H. Penrose, F.R.C.S.—a daughter.

SCOTT.—On July 8, at Elgin, the wife of Dr. G. I. Scott—a son.

WALKER.—On July 6, at East Sheen, the wife of Mr. Alan Walker—a son.

MARRIAGES

DURAS—WALROND.—On June 30, at Brompton, Frank Paul Duras, M.B., to Karen Dorothy Walrond.

MARSDEN—COOPE.—On July 3, at Penarth, Henry Basil Marsden, M.B., to Pamela Jill Coope, B.CHIR.

DEATHS

BIDWELL.—On July 4, at Bloemfontein, South Africa, Charles Hugh Bidwell, M.R.C.S., aged 76.

COOKSON.—On July 7, at Blagdon, Somerset, Reginald George Francis Cookson, L.R.C.P.I.

DOUGLAS-WEBSTER.—On July 2, in South Africa, Edgar Maurice Douglas-Webster, L.R.C.P.E.

FORBES.—On July 8, at Rochester, John Turnbull Thomson Forbes, M.R.C.S., wing-commander, R.A.F. Medical Service retd.

JACOBS.—On July 5, Laurence Jacobs, M.A. Edin., M.B. St. And.

PEPPER.—On July 9, Charles Edward Pepper, M.B. Edin., aged 71.

SMITH.—On July 11, Hugh Bernard Willoughby Smith, F.R.C.S., aged 68.

SYMONS.—On July 3, at Church Crookham, Hants, Sir Thomas Symons, K.B.E., C.S.I., M.R.C.S., aged 76.

Notes and News

NATIONAL INSURANCE CONTRIBUTIONS

THE position of doctors and dentists under the National Insurance and Industrial Injuries schemes has been announced by the Ministry of National Insurance. Doctors and dentists on the *lists of executive councils will be insurable as self-employed* persons (class 2) for their work in that capacity; and the same applies to those engaged in private practice only. The weekly contribution is 6*s.* 2*d.* for a man and 5*s.* 1*d.* for a woman. Those *engaged full-time in hospitals or similar* institutions, or under local or public authorities—e.g., as medical officers of health or in the school medical or dental services—will be insurable as employed persons (class 1) under the National Insurance scheme; they will also be insurable under the Industrial Injuries scheme. This applies, too, where the engagement is not for whole-time services but the duties normally occupy more than half the time and payment is received by salary. Similarly, doctors or dentists engaged by commercial or business organisations who are paid by salary and who spend more than half their time on duties for any one such employer are to be treated as employed persons under both schemes. The total combined National Insurance and Industrial Injuries contribution is 9*s.* 1*d.* a week for a man and 7*s.* 1*d.* for a woman, of which the employee's share is 4*s.* 11*d.* and 3*s.* 10*d.*, respectively.

A NEW CANCER JOURNAL

IN sumptuous shiny format and finely illustrated, the first number of a journal of the American Cancer Society has made its appearance. *Cancer* combines the functions of both *Cancer Research* (U.S.A.) and the *British Journal of Cancer Research* in that it includes papers on the human disease and on experimental work, and selected abstracts from every branch of the subject. Contributions to the first number have set a high standard. They deal with general aspects rather than with individual case-reports. For example, 11 cases of sarcoma arising in irradiated bone are reported, fibroblastic hyperplasias and new growths are reviewed and classified, and the cellular reaction in post-mastectomy lymphœdema is critically examined. The authors of the last-mentioned paper report 6 cases of lymphangiosarcoma developing at an average interval of $12^1/_2$ years from the time of the operation. Experimental work includes the evolution of cancer of the uterine fundus in the rabbit, electrophoretic studies of plasma-proteins in neoplastic disease, and a description of the conversion of a *cancer-resistant to a cancer-susceptible strain of mice by* chemical means. Apart from the usual check on padding with unessential material the space allowed to authors is not limited. The editor is advised by a board including representatives in clinical, radiological, and pathological fields, in research, public health, education, and statistics.

DIRECTORY OF SERVICES

THE National Council of Social Service has published a "handbook of information and directory of organisation of voluntary social services," which Mr. W. G. S. Adams, chairman of the council, introduces with a scholarly survey of their work in this century. Mr. D. H. W. Hall discusses their finance and Miss Eileen Younghusband writes on social service as a profession. The second section summarises the work being done in different fields—such as mental health, blind welfare, and the countryside—and lists the bodies particularly interested in each. The third section, which is the directory proper, gives the name and address and succinct particulars of 300 organisations. The handbook may be obtained from the council, 26, Bedford Square, London, W.C.1 (price 7*s.* 6*d.*).

BEDWETTING

NOCTURNAL enuresis can be a cause of shame and discomfiture for some people throughout life. A committee on Psychiatry and the Law set up *jointly* by the British Medical Association and the Magistrates Association has produced a memorandum[1] which sets out clearly some of the known facts about the condition and offers common-sense guidance for its treatment and management. Poor training in childhood accounts for some 6% of enuretics, and physical abnormality for perhaps 9–10%. Some 85% are suffering from
of function, and in these the psychological back
the condition often repays study; the memorandum is
hardly emphatic enough on this point, though it is me
that the psychiatrist will often be needed in addition
family doctor, either to give more intensive psych
treatment or to assist in diagnosis. In many intr
cases much can be done by good *management* to reli
miserable family situation created by enuresis, e
when it persists in an adult. The memorandum make
point well: the use of a mackintosh sheet or a rubber
for night wear, the practice of rousing the sleeper b
alarm-clock at a time before he habitually passes water,
a certificate from the doctor for an extra soap ration al
to mitigate the nuisance caused by the symptom. All
same it *is*, in most cases, a symptom, and the writers of
memorandum rightly insist on the importance of tr
and the need to study the causes of relapse—give
emotional stress, domestic worry, a nervous break
unsuitable environmental change—"anything in fact t
can upset a somewhat narrow or precarious adaptatio
life." But an adaptation so precarious that it cru
under the ordinary jolts of our lot perhaps deserves a l
superficial and resigned approach from the doctor.

MENTAL DEFICIENCY HOSPITALS UNDER THE

THE new Mental Deficiency Regulations, 1948, make
great changes apart from those necessary to bring the hospit
for this class of patients under the Minister. *The te*
"certified institutions" will no longer apply *to these loc*
authority hospitals, but will be reserved *for places run f*
profit, or at least with private (paying) beds. Medic
officers of institutions vested in the Minister will now b
allowed to sign medical certificates accompanying the orde
This will have little effect in London, where the Lond
County Council have their own certifying officers; but
may simplify things in counties where *the expert from t*
local institution runs clinics and is also asked to do
certifying.

A change of much more interest to *patients* gives sup
tendents the power to grant, on their own respons
two weeks' leave instead of one. Licence for any lo
period must be agreed to by two members of the h
management committee.

VETERINARY EDUCATION

IN his inaugural lecture in the chair of animal path
at Cambridge[1] Prof. W. I. B. Beveridge sketches the dev
ment of the veterinary art and profession. For 5000 y
except during the last century or so, man has depended
animals for land travel as well as for much of his food
clothing. The horse was all-important in military opera
and the invention of the nailed-on horseshoe towards the
of the 9th century A.D. was an event of great internati
importance. Professor Beveridge remarks that the hea
self-criticism of veterinary education by the profession
has perhaps stimulated other criticism, which is sometim
ill informed; and some of the faults in veterinary educati
are common to education in other fields. Outlining the pre
curriculum of five years, he says that students coming up
Cambridge after already taking the 1st M.B. will take
years to qualify; which makes one wonder *if so long a t*
is justifiably spent on the course. The veterinary stu
should obtain a wide scientific background at Cambr
but, as we said in reviewing the second report of the Lo
Committee,[2] the importance of *illustrating* general pr
by reference to the animals and problems with whi
student will deal after qualifying must be kept in mind
is largely recognised in bacteriology and pathology,
perhaps particularly important in physiology, beca
medicine there is a tendency to focus increasing att
on the study of human function. It is a little surpri
hear that for anatomy the dog is regarded as probably
most suitable type of animal, though ruminants are so
more important to veterinarians *and sheep should be* m
obtainable for dissection.

Perhaps the most interesting part of the lecture is
dealing with postgraduate teaching and research. The
research-worker learns much by precept and example,
there is scope for formal training in basic principles and

[2] *Lancet*, 1944, i, 735.

iques. Professor Beveridge says that the student should couraged to read the lives of the great scientists; the tant rôle of the so-called chance observations and ion, together with the general principles of planning iments, should be explained to him.

ACCESS TO WATER GATHERING-GROUNDS

OSE who are responsible for gathering and purifying are in the habit of arguing that rigid restrictions on s to gathering-grounds are essential unless costly new ying plant is to be installed. A subcommittee of the ral Advisory Water Committee, appointed by the Minister ealth, takes a different view. In its report,[1] published lest the subcommittee finds that, if the water is suitably ied, there is no reason for excluding the public from ering-ground as such; boating and fishing on reservoirs sometimes be permitted under rigorous control, but no ing should be allowed and the public should be generally uded from the banks. Land should be put to the utmost cultural use; but sewage from human habitations should revented from getting into the reservoir, and farmyard nure must not be allowed to drain into feeder streams or rwise to reach the reservoir. Subject to these limitations, *the avoidance of large crowds*, the committee "can see justification, on grounds of water purity, for prohibiting ss by walkers, cyclists, or motorists to the remainder of gathering ground." Camping and caravanning should, ever, be restricted to approved sites; and it is suggested t camping organisations might publish maps showing mitted sites.

AMENDMENTS TO NATIONAL FORMULARY

EVERAL changes in the *National Formulary* will take ct from Aug. 1. There will be three new mouth-washes—utorium acidi tannici; collut. sodii chloridi co. (sod. or. gr. 8 and sod. bicarb. gr. 2 to the ounce of peppermint ter); and collut. zinci sulphatis et zinci chloridi co. Other litions will be: pigmentum arseni et ipecacuanhæ, and ella acidi acetylsalicylici et quininæ co., containing aspirin 3, phenacetin gr. 3, caffeine gr. $^{1}/_{4}$, and quinine sulphate $^{1}/_{4}$. Gargaresina acidi tannici and nebula penicillini will be eted.

ASSOCIATION OF MUNICIPAL SPECIALISTS

AT a special meeting on June 28, members unanimously eed that this association should continue to serve whole-e medical specialists. In future it is to be known as the ociation of Whole-Time Salaried Specialists, and all whole-e specialists will be eligible for membership. Inquiries uld be addressed to the association's office at 45, Lincoln's n Fields, London, W.C.2 (Tel.: Holborn 3474).

DENTAL CARE OF THE YOUNG

SPEAKING last week in Liverpool at the annual meeting of British Dental Association, Mr. P. G. Capon, the new sident, said that it was illogical that the dental care of preschool child should be the responsibility of the Minister Health, that of the school child the responsibility of the nister of Education, and that of the adolescent nobody's ponsibility. The inadequate provision for children would tinue to produce the familiar broken-down dentition of the ult. It seemed tragic, said Mr. Capon, that the dental fession had not been asked to assist in establishing a structive plan, which in time would have done much to ntrol the situation.

---

yal Appointments

The following appointments to Queen Mary's Household ve been gazetted:

urist, Mr. John McLaggan; surgeon-oculist, Mr. J. G. Milner; l surgeon-dentist, Mr. Douglas Lennie.

w Chief Nursing Officer

The Minister of Health has appointed Miss E. Cockayne be chief nursing officer as from July 1, in succession to Dame therine Watt, who has become chief nursing adviser. ss Cockayne was formerly matron at the Royal Free spital.

University of Cambridge

On June 22 the degrees of M.B. and B.CHIR. were conferred by proxy on D. J. Morton.

University of London

Dr. J. L. D'Silva has been appointed to the university chair of physiology tenable at London Hospital medical college, as from Oct. 1.

Dr. D'Silva, who graduated PH.D. at London University in 1931 and D.SC. in 1940, qualified from St. Bartholomew's Hospital in 1942. He held appointments there as demonstrator in physiology, house-physician, and chief assistant; and he was later an assistant physician in the E.M.S. In 1943 he became M.R.C.P. Two years ago he was appointed reader in physiology at Bart's. Dr. D'Silva has published articles on the dismutation of disulphides, the effect of adrenaline on serum potassium, and the treatment of arterial hypertension.

University of Manchester

Dr. E. W. Anderson has been appointed professor of psychiatry and director of the university department.

Dr. Anderson qualified M.B. at Edinburgh in 1923 and held hospital appointments in Edinburgh and Dover. He graduated M.D. in 1927, and in 1930 became M.R.C.P. In 1929 he was appointed assistant medical director at the Maudsley Hospital, and in 1935 medical director of the Cassel Hospital. In 1937–38, as a Rockefeller fellow, he spent a year at Continental clinics, and on his return was appointed consulting psychiatrist to Devonshire county council. From January, 1940, he served in the R.N.V.R. as a neuropsychiatric specialist, attaining the rank of surgeon-commander. In 1946 he was elected F.R.C.P. Last year Dr. Anderson returned to the Maudsley Hospital as a physician, and he has taught at the institute of psychiatry there and at the Postgraduate Medical School of London.

University of Liverpool

At a congregation on July 3 the following degrees were conferred:

M.D.—G. M. Ardran, B. K. Ellenbogen, E. W. T. Evans, K. B. Gibson, A. L. Latner, Ivan Leveson, J. M. Swithinbank.

M.S.—Raphael Marcus; R. A. Smith (in absentia).

M.Rad.—H. G. Frank, A. M. Fraser, Ifan Pierce-Williams, H. L. Ross, G. D. Scarrow, W. I. Walker, John Winter.

M.B., Ch.B.—H. T. G. Williams (second-class honours), Cecil Alexander, June P. Arnold, W. B. Ashby, D. J. B. Ashley, Mary F. Barrie, A. J. Bathurst, J. F. Bell, L. B. Bruce, C. R. Cartwright, G. D. Currie, Anthony Dalzell, F. J. Dunn, E. C. Edwards, H. L. Goffman, T. D. H. Gray, Ellis Gruber, Elspeth M. Hill, Sylvia S. C. Hinde, C. I. Hood, A. W. Howel-Evans, C. O. Le C. Hughes, J. C. Humber, John Humphreys, Mair Humphreys, P. F. Jack, Dorothy M. Jennings, Elizabeth M. Johnson, C. H. Jones, W. W. Jones, Peter Kilburn, J. G. Kingan, Christine Lewis, J. F. Lynch, A. G. Mackinnon, Mary K. Marchant, Geoffrey Marsh, Eric Martindale, D. N. Menzies, Margaret J. Miller, Helen T. Morgan, E. G. Myerscough, James O'Donoghue, Mary G. O'Hare, W. R. Parkes, Leslie M. Pinkerton, Gwyneth E. Pritchard, Millicent M. C. Regan, Freda M. Roberts, J. R. Roberts, R. V. Roberts, Kathleen M. Roby, Barbara F. M. Shirley, S. S. Swift, H. M. Thomas, Harral Thompson, Joyce K. Watkin, W. K. M. C. Watkins, D. B. Wilkinson.

University of Sheffield

The following appointments are announced:

Dr. T. Summerfield King, lecturer in anatomy; Mr. A. A. Carlyle, lecturer in physiology; Mrs. Joan Laird, M.B., research assistant in medicine; Dr. John Lorber, research assistant in child health; Mr. G. Y. Kennedy, research-worker in the department of pathology under the auspices of the British Empire Cancer Campaign; and Dr. Gilbert Forbes, senior lecturer in charge of the new department of forensic medicine.

University of Nottingham

Nottingham University College has been granted full university status. Founded in 1881, the college was the first in this country to be formed by municipal action. Lord Trent is to be the first chancellor of the university; and the vice-chancellor will be Mr. B. L. Hallward, formerly headmaster of Clifton College.

University of Glasgow

The following degrees and diplomas have lately been conferred:

M.D.—William Fowler, J. A. C. Knox, A. M. Lamont (in absentia), Robert Leishman, C. E. B. Lynch, Jean M. Neville, J. A. O'Connor, J. M. Rosie.

M.B., Ch.B.—D. C. Aird, G. W. Allan, J. B. Allan, J. M. Anderson, D. S. Andrew, Robert Bain, Agnes R. Baird, J. W. Baird, G. D. Ballantyne, Janet M. Bell, Verne A. Bennett, John Bingham, J. F. Boyd, Doris J. H. Brechin, A. M. Brown, J. H. L Bruce, Alan Bryce, J. R. Bryson, R. A. Buchanan, G. I. Cameron, Douglas Campbell, A. M. Chalmers, Martha A. A. Chisholm, Jeanne M. Clarke, E. N. Coleman, Marion H. C. Cornock, P. M. Crawford, R. J. Cruickshank, D. P. Daly, John Dickson, James Donnelly, R. L. Duncan, J. F. Dunn, I. D. Ferguson, T. B. Ferguson, Frederick Fischbacher, A. M. Fotheringham, Thomas Gardner, Jean Gibson,

Winifred A. Gibson, Ian Gilfillan, O. C. L. Gloster, W. F. Gordon, C. P. D. Grant, R. N. Greenhalgh, Erika P. Grossfeld, Matthew Hamilton, R. W. Harrington, J. M. Hiddleston, Charles Hodes, J. F. Kay, Thomas Kempton, Marshall Kennedy, G. M. Kerr, P. M. Kinloch, Lilias H. Liston, Edith B. Loudon, C. M. Macaulay, I. G. W. McDonald, I. R. Macdonald, J. A. McFadzean, J. P. R. MacFarlane, H. C. McGilp, G. S. McGregor-Robertson, S. S. Macilwain, G. K. K. McKay, Anne E. C. MacKinnon, Janet J. Mackintosh, Christina I. Maclean, Sheena D. MacLeod, William McRoberts, R. D. Mairs, W. S. Manderson, W. W. Marshall, R. H. M. Mavor, A. W. Morrison, E. D. Morton, J. W. Muir, Mairi C. Nicolson, Nanette H. Nisbet, Walter Norris, J. L. Patterson, P. B. Pullar, Rhona A. Reid, James Ritchie, J. M. Robertson, Ellen M. A. Russell, Hazel E. A. Saunders, Hope B. T. Scott, W. G. Semple, I. C. Seymour, Hazel M. Short, J. B. Sloan, A. N. Smith, A. I. Smith, Anne F. Smith, G. D. Smith, Woolfred Sniper, Francis Stewart, A. E. Stuart, Peter Sullivan, H. I. Tankel, A. C. S. Taylor, A. J. Tear, J. S. Ternie, Henry Thompson, I. B. Thomson, W. M. S. Thomson, R. N. Thorburn, I. M. Todd, Janet F. Walker, Joan L. Walker, A. D. Wallace, P. N. Waugh, D. H. Wilson, D. L. Wilson, W. M. Wilson, Jean-Margaret H. Wotherspoon.

D.P.H.—A. S. Brodie, Betsy Brown, H. B. Brown, L. G. Bruce, William Cormack, A. P. Curran, G. G. Lindsay, J. M. McEwan, Margaret W. Macgregor, James Maclachlan, Iain Macleod, A. N. MacPhail, G. A. Mills, May B. Paterson, J. S. M. Pollock, I. M. Richardson, E. M. Sewell, James Smith, John Thompson, R. T. B. Watson, Margaret L. Williamson.

Royal College of Physicians of London

The Mitchell lecture, to be given by Dr. Robert Coope, has been postponed until Thursday, Nov. 18.

Royal College of Surgeons of England

At a meeting of the council on July 8, Lord Webb-Johnson was re-elected president for an eighth year. Mr. L. E. C. Norbury and Mr. V. Zachary Cope were elected vice-presidents.

The following were elected lecturers for the ensuing year:

Hunterian professors: Mr. Hamilton Bailey, parotidectomy; Prof. Shafik Shalaby, amœbic liver abscess; Mr. Terence Cawthorne, labyrinthine vertigo; Dr. W. S. C. Copeman, lumbar fibrositis; Mr. R. W. Raven, malignant melanoma; Mr. M. W. C. Oldfield, hare-lip and cleft palate; Mr. C. H. Gray, painful hip-joint; Mr. A. C. Kanaar, pulmonary atelectasis; Mr. J. G. Bonnin, diastasis of the tibiofibular syndesmosis; Mr. D. F. E. Nash, development of micturition control; Mr. W. S. Lewin, acute subdural and extradural hæmatoma in closed head injuries; Mr. Robert Roaf, residual disability following injuries of the peripheral nerves of the upper extremity; Mr. John Loewenthal, intractable ulceration of the leg, with special reference to streptomycin; and Mr. R. A. R. Taylor, acute pancreatitis. *Arris and Gale lecturers:* Mr. R. K. Bowes, infra-red photographic studies of superficial veins in the female; and Prof. R. H. Goetz, vascular diseases, with special consideration of clinical plethysmography and the surgical physiology of the autonomic nervous system. *Erasmus Wilson demonstrators:* Mr. C. E. Shattock, Dr. L. W. Proger, Dr. R. M. Haines, and Mr. Guy Blackburn. *Arnott demonstrators:* Mr. P. H. Mitchiner, Mr. R. J. Last, and Dr. F. S. Gorrill.

A diploma of membership was granted to R. H. R. Aston. Diplomas of fellowship were granted to the following:

J. W. Ardagh, D. W. Bain, P. B. Banaji, C. R. Berkin, K. P. Bhargava, B. E. Blair, S. M. Boctor, C. A. Brown, J. A. Carr, Richard Chignell, E. F. Chin, R. I. Cohen, J. C. F. Cregan, V. H. Cumberland, H. C. Dales, H. P. Dunn, E. M. Elmhirst, D. V. Evans, J. B. Farquhar, Thomas Faulkner, James Freeman, L. B. Gottlieb, Evan Griffiths, E. V. Hope, N. N. Iovetz-Tereshchenko, K. G. Jayasekera, D. H. Jenkins, A. R. Johnson, C. J. Kaplan, A. E. Kark, Z. K. Kazi, R. R. Klein, J. B. Kyle, D. W. Lacey, L. P. Lassman, Tobias Levitt, T. G. E. Loosemore, B. C. H. Luker, A. M. Macarthur, A.-R. Makey, Margaret M. Mason, C. K. P. Menon, N. H. Morgan, I. F. K. Muir, C. I. Murphie, H. H. Nixon, K. R. Pai, D. T. H. Paine, Matthias Paneth, Eric Parry, V. T. Pearse, P. F. Philip, J. H. Phillips, W. J. Pullen, P. E. Rees-Davies, A. G. Riddell, S. S. Rose, Richard Rowlandson, Heinz Salz, C. S. Savage, P. H. Schurr, C. G. Scorer, R. I. R. Skelley, T. B. Smiley, W. K. Smiley, Ross Smith, Rupert Solley, J. P. Stephens, [illegible] Tagart, J. E. Talbot, V. R. Thayumanaswan[illegible] Turnbull, J. P. Turney, B. A. Ward, E. A. [illegible] M. F. Windsor, W. S. Wood, J. J. Woodward.

The following diplomas were awarded jointly with the Royal College of Physicians:

D.P.M.—P. A. Adam, G. B. Barker, Catherine H. S. Begg, S. H. Beckner, Daniel Cappon, R. O. Cooke, John Donnelly, Audrey L. Ferguson, Margaret W. Ferguson, G. S. Gladstone, R. S. Hodge, D. W. K. Kay, M. R. Leahy, J. F. McHarg, Rangasamy Natarajan, D. J. Petit, G. S. Prince, A. S. L. Rae, A. G. Silver, R. H. F. Smith.

D.L.O.—D. J. J. Ackermann, A. C. Cox, N. S. Daw, D. A. Draffin, B. I. Eames, I. N. Fulton, Hrisikesh Hazra, P. H. Huggill, M. S. Khan, R. A. Lindsay, R. L. McFadden, E. A. Malkin, Mohammad Mohsin, A. T. P. Pitt, D. M. Stevens, J. G. Stenham.

D.A.—R. I. W. Ballantine, M. M. Boyle, A. S. Brown, J. R. Esplen, J. K. Farquhar, Violet Fry, A. H. Grannt, D. J. Hadfield, Marie E. Hill, D. A. B. Hopkin, M. D. C. Hosford, Howard Jackson, P. D. Johnson, R. H. N. Lake, H. L. Leaming, W. J. Lewis, L. H. Lithman, P. F. M. MacDonagh, Alistair Mackenzie, G. A. Mandow, Timothy Marshall, J. G. Millers, John Moore, W. D. Munro, C. J. K. Orr, Anthony Owen-Flood, H. P. L. Ozorio, C. H. Podesta, E. S. Pope, T. R. Steen, Mark Swerdlow, D. V. Thomas, Frances M. Ulyatt, Claude Umagilliya, Harry Walker, A. T. Welsh, H. B. Young.

The following hospitals have been recognised for the final fellowship examination:

Staincliffe County Hospital, Dewsbury (resident surgical officer); Northampton General Hospital (resident surgical officer, surgical registrar, and orthopædic house-surgeon—additional recog St. Andrew's Hospital, Dollis Hill (senior and junior house- Central Middlesex County Hospital (three house-surgeons); C Hospital, Whiston (resident surgical officer, class 3 (rehabilit officer, and general house-surgeon).

Royal College of Surgeons in Ireland

The following have received the diploma of fellowship:

G. I. Fenton, E. A. McGivern, S. N. Rutherford, E. F. Sha

International Students' Congress

The Students' International Clinical Congress, opened in London on July 6, was continued at Oxford Tuesday; and on Monday the delegates will go on Birmingham. Organised by the British Medical Studen Association, this is believed to be the first conference of sort.

Royal Society of Medicine

As announced last week Sir Henry Dale, O.M., has be elected president of this society in succession to Sir Maur Cassidy. The following officers and other members of cou were also elected at the annual meeting of fellows on July 6

Hon. secretaries.—Mr. W. A. Pool and Dr. A. T. M. Wilson.
Hon. treasurers.—Dr. Charles Newman and Mr. L. R. Broste
Hon. librarians.—Mr. E. K. Martin and Dr. Thomas Hunt.
Hon. editors.—Mr. E. A. Crook and Dr. E. R. Cullinan.
Other members of council.—Miss Geraldine Barry, Dr. E. E Boland, Dr. R. R. Bomford, Sir Ernest Rock Carling, Dr. Macdon- Critchley, Dr. Maurice Davidson, Sir Gordon Gordon-Taylor, Dr. Charles Harris, Dr. Bernard Hart, Dr. J. C. Hawksley, Mr. J. F Hunter, Dr. F. Avery Jones, Mr. D. H. Patey, Mr. A. E. Porrit Mr. R. H. O. B. Robinson, and Sir Henry Tidy.

Royal Medico-Psychological Association

Members of this association had the opportunity, at their annual dinner on July 7, to hear something about the work of the Churches Council of Healing. The Bishop of Lincoln, in proposing the toast of Medicine, told how this grow body came into being as the Guild of Health, founded by t late Archbishop William Temple. Knowing of clergy w were capable of spiritual healing, Archbishop Temple wi to bring them into touch with psychiatrists, in order th their work might be complementary. At a joint meeti the Council of Healing with the British Medical Associ some years ago, it was agreed that several doctors s join the committees of the council, and the collaborati the two groups of healers has in some cases, the Bishop s given remarkable and mysterious results. Dr. A. Pool member of the council, in replying to the toast described a inexplicable recovery which he had recently seen.

Dr. R. Ström-Olsen, who proposed The Guests, appea to Miss D. M. Smith, president of the General Nursing Coun to work for the better status of the mental nurse; wh Miss Smith was evidently ready to do. Mr. John Edwar M.P., in proposing the toast of the association, spoke a l of the National Health Service, and of the Governme wish to create conditions under which doctors can work t the greatest advantage of their patients; while Dr. W. Re Thomas, the president, who replied on behalf of the association, assured Mr. Edwards that the incidence of ment breakdown among public men is very small. He seemed les satisfied with their works than their health, however, remarki that the present high incidence of anxiety depression in t public is attributed by some to our legislators.

After receiving the Cameron prize in Edinburgh for h work on the effects of drugs on the thyroid gland, Prof. E. Astwood, endocrinologist at the Pratt Diagnostic Hos in Boston, is in London until July 23, lecturing for the B Medical Association and carrying out a series of vi endocrinological departments arranged by the British Co

HE AMERICAN TEACHING HOSPITAL*

ELI DAVIS

M.D., M.Sc. Manc., M.R.C.P.

N order to attract the best men as teachers, a medical ool must have great prestige and a good deal of money, alternatively it must have a philosophy or creative ssion which will draw to it fine minds even if the school elatively poor.

he character of the institution is determined by the ality of its teachers and of its students; and in the ding schools of the United States there is an admirable dency for teachers and students to be regarded as ior and junior fellow workers in the same field. There too, a healthy inclination by medical schools to choose ung departmental chiefs, who get responsibility while ey are most creative. At most schools full-time chiefs e preferred to those serving part-time, but a certain sticity is evident in the pursuit of this principle. At arvard, for example, the chief is considered to be full-me and is given a salary which makes him relatively dependent of outside sources of income. Nevertheless, e is allowed some private practice, mostly on the hospital remises, and may retain the fees: the psychological tisfaction thus derived seems even more important an the financial return. Other schools allow their iefs private practice, but the fees must go to the epartment.

The needs of the hospital, the student, and the patient ake it essential that the chief selected devotes most of is time to the hospital. But there is an honoured lace for part-time teachers of distinction. Outstanding linicians in private practice who can teach and who ke to teach should be given a part in the education of he students.

DEPARTMENTAL ORGANISATION

In many American hospitals and medical schools there s a single department of medicine, surgery, pædiatrics, bstetrics, and so on, each with a chairman or chief. hould the department of medicine include under one hief the departments of neurology and dermatology? ikewise, should the department of surgery include nder its chief the departments of orthopædics and tolaryngology and ophthalmology? In some leading chools the tendency is to put all the subdivisions of the eld of medicine or the field of surgery (and so on) under ne chairman. This is convenient because it allows for tegrated teaching, the smoother allocation of beds, and ider experience for the intern; and it is easier for a irector or a dean to deal with one head than with several eads. But the best men seem to flourish only when they ave real autonomy and responsibility for the development nd fostering of their specialty. The administrative load n chiefs of departments was great enough even in the bsence of further responsibility for the specialties, and eriously interfered with their availability for teaching nd for research. To add to their responsibilities in this ay would, in some cases, be crushing. After all, it should e the duty of the director and dean to administer, to tegrate, and to correlate.

CURRICULUM

Many American medical students have had four years f college training before entering medical school, and ractically all graduates take an internship: these nportant facts influence the form of the curriculum. t many schools the student begins his real clinical raining two and a half years before graduation. Some uthorities assert that this is too late, and at certain schools students begin clinical work four years before graduation. Other teachers, however, fear that this early introduction to the wards may cause neglect of the basic sciences through the immediate interest of the patient.

At some places correlation courses have been well developed; for example, in physiology, when fluid balance is being discussed, patients with œdema and patients with dehydration are presented. Correlation is, however, far too much in one direction; while clinical topics are introduced early, there is not enough of the other form of correlation—for example, calling in the physiologist when the physician is confronted with a case of myelitis, or calling in the biochemist for personal consultation when the results of jaundice tests are baffling. Correlation should be two-way. Biochemistry and physiology should continue to be taught in the later years of the course.

To make for better correlation, Rochester medical school has initiated some double professorships—for example, there is a professor of bacteriology *and* internal medicine, and also a professor of medicine and psychiatry.

At some centres the emphasis at clinical pathological conferences is no longer on diagnosis but on the interpretation of symptoms and signs in terms of biochemistry and modified physiology; indeed one aim of correlation is to get physiological thinking at all levels. The experiment is being tried of assigning the student to a patient rather than to a department: so if a patient is transferred from one department to another, the student is still concerned with him.

Dr. Alan Gregg has succinctly outlined the essential aims of training. The student must be taught to observe accurately and comprehensively. He must learn to reason soundly about observations made. He must pay attention to the observations of others, and so learn how to use a good medical library. He should approach the sick with a sense of compassion.

Biochemistry is the dominant discipline in many medical schools. It is felt, however, that just as this is a biochemical era, biophysics is likely to make outstanding contributions in the next decade, and the biophysicist and his department are becoming more frequent in progressive medical schools.

Note may be taken of the attractive arrangement in Dr. A. Rich's department of pathology in Johns Hopkins medical school. Here, in addition to the usual services, a special room is devoted to the pathology of each clinical division—e.g., gynæcology, dermatology, and ophthalmology. Working in these rooms are not only the permanent staff but the assistant resident of the clinical department concerned, who remains there for a year, acting as a living link between his clinical division and the department of pathology. At the same time he gets first-rate grounding in pathology.

METHODS OF TEACHING

At Yale no courses are compulsory; the idea is to make the student want to acquire the facts rather than to teach him all the facts. Moreover, since the curriculum is not crowded, the student is left with some spare time. At Yale no student is recommended for his degree until, as well as passing his final examination, he has presented a satisfactory thesis. This thesis is a valuable educational weapon; it teaches the student to think and observe, and to make use of a medical library.

A successful experiment is being conducted at Rochester, New York. Each year a number of stipends is offered to students to enable them to spend an extra year working on any subject in the medical curriculum that they choose; and during this time, in which they pay no fees, they are regarded as junior members of the teaching staff. This arrangement encourages the good

Royal College of Physicians of London

The Mitchell lecture, to be given by Dr. Robert Coope, has been postponed until Thursday, Nov. 18.

Royal College of Surgeons of England

At a meeting of the council on July 8, Lord Webb-Johnson was re-elected president for an eighth year. Mr. L. E. C. Norbury and Mr. V. Zachary Cope were elected vice-presidents.

The following were elected lecturers for the ensuing year:

Hunterian professors. Mr. Hamilton Bailey, parotidectomy; Prof. Shafik Shalaby, amœbic liver abscess; Mr. Terence Cawthorne, labyrinthine vertigo; Dr. W. S. C. Copeman, lumbar fibrositis; Mr. R. W. Raven, malignant melanoma; Mr. M. W. C. Oldfield, hare-lip and cleft palate; Mr. C. H. Gray, painful hip-joint; Mr. A. C. Kanaar, pulmonary atelectasis; Mr. J. G. Bonnin, diastasis of the tibiofibular syndesmosis; Mr. D. F. E. Nash, development of micturition control; Mr. W. S. Lewin, acute subdural and extradural hæmatoma in closed head injuries; Mr. Robert Roaf, residual disability following injuries of the peripheral nerves of the upper extremity; Mr. John Loewenthal, intractable ulceration of the leg, with special reference to streptomycin; and Mr. R. A. R. Taylor, acute pancreatitis. *Arris and Gale lecturers:* Mr. R. K. Bowes, infra-red photographic studies of superficial veins in the female; and Prof. R. H. Goetz, vascular diseases, with special consideration of clinical plethysmography and the surgical physiology of the autonomic nervous system. *Erasmus Wilson demonstrators:* Mr. C. E. Shattock, Dr. L. W. Proger, Dr. R. M. Haines, and Mr. Guy Blackburn. *Arnott demonstrators:* Mr. P. H. Mitchiner, Mr. R. J. Last, and Dr. F. S. Gorrill.

A diploma of membership was granted to R. H. R. Aston. Diplomas of fellowship were granted to the following:

J. W. Ardagh, D. W. Bain, P. B. Banaji, C. R. Berkin, K. P. Bhargava, B. E. Blair, S. M. Boctor, C. A. Brown, J. A. Carr, Richard Chignell, E. F. Chin, R. I. Cohen, J. C. F. Cregan, V. H. Cumberland, H. C. Dales, H. P. Dunn, E. M. Elmhirst, D. V. Evans, J. B. Farquhar, Thomas Faulkner, James Freeman, L. B. Gottlieb, Evan Griffiths, E. V. Hope, N. N. Iovetz-Tereshchenko, K. G. Jayasekera, D. H. Jenkins, A. R. Johnson, C. J. Kaplan, A. E. Kark, Z. K. Kazi, R. R. Klein, J. B. Kyle, D. W. Lacey, L. P. Lassman, Tobias Levitt, T. G. E. Loosemore, B. C. H. Luker, A. M. Macarthur, A.-R. Makey, Margaret M. Mason, C. K. P. Menon, N. H. Morgan, I. F. K. Muir, C. I. Murphie, H. H. Nixon, K. R. Pai, D. T. H. Paine, Matthias Paneth, Eric Parry, V. T. Pearse, P. F. Philip, J. H. Phillips, W. J. Pullen, P. E. Rees-Davies, A. G. Riddell, S. S. Rose, Richard Rowlandson, Heinz Salz, C. S. Savage, P. H. Schurr, C. G. Scorer, R. I. R. Skelley, T. B. Smiley, W. K. Smiley, Ross Smith, Rupert Solley, J. P. Stephens, W. D. Sturrock, R. E. B. Tagart, J. E. Talbot, V. R. Thayumanaswami, D. J. Tibbs, Kenneth Turnbull, J. P. Turney, B. A. Ward, E. A. Williams, J. N. Wilson, M. F. Windsor, W. S. Wood, J. J. Woodward.

The following diplomas were awarded jointly with the Royal College of Physicians:

D.P.M.—P. A. Adam, G. B. Barker, Catherine H. S. Begg, S. H. Bockner, Daniel Cappon, R. O. Cooke, John Donnelly, Audrey L. Ferguson, Margaret W. Ferguson, G. S. Gladstone, R. S. Hodge, D. W. K. Kay, M. R. Leahy, J. F. McHarg, Rangasamy Natarajan, D. J. Petit, G. S. Prince, A. S. L. Rae, A. G. Silver, R. H. F. Smith.

D.L.O.—D. J. J. Ackermann, A. C. Cox, N. S. Daw, D. A. Draffin, B. I. Eames, I. N. Fulton, Hrisikesh Hazra, P. H. Huggill, M. S. Khan, R. A. Lindsay, R. L. McFadden, E. A. Malkin, Mohammad Mohsin, A. T. P. Pitt, D. M. Stevens, J. G. Stonham.

D.A.—R. I. W. Ballantine, M. M. Boyle, A. S. Brown, J. R. Esplen, J. K. Farquhar, Violet Fry, A. H. Grannt, D. J. Hadfield, Marie E. Hill, D. A. B. Hopkin, M. D. C. Hosford, Heward Jackson, P. D. Johnson, R. H. N. Lake, H. L. Leaming, W. J. Lewis, L. H. Lithman, P. F. M. MacDonagh, Alistair Mackenzie, G. A. Mandow, Timothy Marshall, J. G. Millers, John Moore, W. D. Munro, C. J. K. Orr, Anthony Owen-Flood, H. P. L. Ozorio, C. H. Podesta, E. S. Pope, T. R. Steen, Mark Swerdlow, D. V. Thomas, Frances M. Ulyatt, Claude Umagillya, Harry Walker, A. T. Welsh, H. B. Young.

The following hospitals have been recognised for the final fellowship examination:

Staincliffe County Hospital, Dewsbury (resident surgical officer); Northampton General Hospital (resident surgical officer, surgical registrar, and orthopædic house-surgeon—additional St. Andrew's Hospital, Dollis Hill (senior and junior house- Central Middlesex County Hospital (three house-surgeons); C Hospital, Whiston (resident surgical officer, class 3 (rehabil officer, and general house-surgeon).

Royal College of Surgeons in Ireland

The following have received the diploma of fellowship.

G. I. Fenton, E. A. McGivern, S. N. Rutherford, E. F. Sh

International Students' Congress

The Students' International Clinical Congress, opened in London on July 6, was continued at Oxford Tuesday; and on Monday the delegates will go Birmingham. Organised by the British Medical Stu Association, this is believed to be the first conference of sort.

Royal Society of Medicine

As announced last week Sir Henry Dale, O.M., has elected president of this society in succession to Sir Ma Cassidy. The following officers and other members of c were also elected at the annual meeting of fellows on July 6

Hon. secretaries.—Mr. W. A. Pool and Dr. A. T. M. Wilson.
Hon. treasurers.—Dr. Charles Newman and Mr. L. R. Broster.
Hon. librarians.—Mr. E. K. Martin and Dr. Thomas Hunt.
Hon. editors.—Mr. E. A. Crook and Dr. E. R. Cullinan.

Other members of council.—Miss Geraldine Barry, Dr. E. Boland, Dr. R. R. Bomford, Sir Ernest Rock Carling, Dr. Macdo Critchley, Dr. Maurice Davidson, Sir Gordon Gordon-Tayl Dr. Charles Harris, Dr. Bernard Hart, Dr. J. C. Hawksley, Mr. J. Hunter, Dr. F. Avery Jones, Mr. D. H. Patey, Mr. A. E. Porri Mr. R. H. O. B. Robinson, and Sir Henry Tidy.

Royal Medico-Psychological Association

Members of this association had the opportunity, at their annual dinner on July 7, to hear something about the work of the Churches Council of Healing. The Bishop of Linco in proposing the toast of Medicine, told how this grow body came into being as the Guild of Health, founded by the late Archbishop William Temple. Knowing of clergy w were capable of spiritual healing, Archbishop Temple wi to bring them into touch with psychiatrists, in order their work might be complementary. At a joint meetin the Council of Healing with the British Medical Associa some years ago, it was agreed that several doctors sh join the committees of the council, and the collaboratio the two groups of healers has in some cases, the Bishop s given remarkable and mysterious results. Dr. A. Poo member of the council, in replying to the toast described inexplicable recovery which he had recently seen.

Dr. R. Ström-Olsen, who proposed The Guests, ap to Miss D. M. Smith, president of the General Nursing Cou to work for the better status of the mental nurse; wh Miss Smith was evidently ready to do. Mr. John Edwar M.P., in proposing the toast of the association, spoke a l of the National Health Service, and of the Government wish to create conditions under which doctors can work t the greatest advantage of their patients; while Dr. W. Re Thomas, the president, who replied on behalf of the ass ciation, assured Mr. Edwards that the incidence of menta breakdown among public men is very small. He seemed le satisfied with their works than their health, however, remark that the present high incidence of anxiety depression in th public is attributed by some to our legislators.

After receiving the Cameron prize in Edinburgh for h work on the effects of drugs on the thyroid gland, Prof E. Astwood, endocrinologist at the Pratt Diagnostic Hos in Boston, is in London until July 23, lecturing for the B Medical Association and carrying out a series of vis endocrinological departments arranged by the British Cou

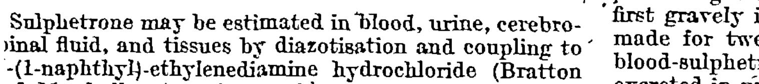
ULPHETRONE: THERAPEUTICS AND TOXICOLOGY *

GEORGE BROWNLEE
B.Sc. Glasg., Ph.D. Lond.
rom the Wellcome Physiological Research Laboratories, Beckenham, Kent

HE discovery in these laboratories of the chemo-apeutic activity of diaminodiphenylsulphone (Buttle . 1937) stimulated a search for derivatives having the iency of the parent drug but not its undesirable city. One derivative, tetrasodium 4 : 4-bis (γ-phenyl-ylamino)-diphenylsulphone-$\alpha : \gamma : \alpha' : \gamma'$-tetrasulph-te, given the registered name 'Sulphetrone,' was first ared in 1936 and attracted attention on re-examina- in 1941 by reason of its freedom from toxicity and potent antituberculotic activity.

rownlee et al. (1948) have described its structure, chemical physical properties, pharmacology, experimental therapy, possible clinical uses; and Brownlee and Kennedy (1948a) e described its suppressive effect on progressive experi-ital tuberculosis in guineapigs. The drug was found to be teriostatic and, in common with other sulphones, incapable liminating the infective organism from animal tissue. In econd study Brownlee and Kennedy (1948b) have shown t sulphetrone is more efficient than 'Promin' in protecting laboratory animal against experimental tuberculosis, and t it is synergic with streptomycin. A clinical evaluation, ortunately restricted to a limited series, was made by digan et al. (1947). The chemical preparation of sulphetrone been described by Gray and Henry (1936) and by Buttle al. (1938).

Sulphetrone is a cream-coloured amorphous material itaining 5–7% water. Its molecular weight is 892·5 d its probable constitution is as follows:



$$\text{H}_5\text{—}\underset{\text{SO}_3\text{Na}}{\text{CH}}\text{—CH}_2\text{—}\underset{\text{SO}_3\text{Na}}{\text{CH}}\text{—NH—C}_6\text{H}_4\text{—SO}_2\text{—C}_6\text{H}_4\text{—NH—}\underset{\text{SO}_3\text{Na}}{\text{CH}}\text{—CH}_2\text{—}\underset{\text{SO}_3\text{Na}}{\text{CH}}\text{—C}_6\text{H}_5$$

It is insoluble in alcohol and other organic solvents but ceedingly soluble in cold water; 40% (w/v) solutions e stable when neutral or slightly alkaline, and a 60% lution may be autoclaved; 10% solutions are isos-otic, but 20% and even 40% solutions are well tolerated tramuscularly.

ESTIMATION

Sulphetrone may be estimated in blood, urine, cerebro-inal fluid, and tissues by diazotisation and coupling to -(1-naphthyl)-ethylenediamine hydrochloride (Bratton nd Marshall 1939), the resultant dye being measured lorimetrically or, better, absorptiometrically. Since lphetrone mixes intimately with precipitated proteins, e conditions governing its optimal recovery were etermined experimentally. They are critical and ust be rigidly respected to obtain 90% recoveries of lphetrone:

To 5 ml. of $N/1$ hydrochloric acid 0·5 ml. of blood or other ody fluid is added and mixed well; 2·0 ml. of 12% (w/v) ichloracetic acid is added, and the well-mixed solution is ltered immediately through a no. 5 Whatman paper and passed until brilliant; 3 ml. of filtrate is mixed with 05 ml. of 0·3% fresh (weekly) sodium nitrite and left for min.; 0·05 ml. of 1·5% ammonium sulphamate is now dded, and the solution left for 2 min. Finally 0·05 ml. of 1% N-(1-naphthyl)-ethylenediamine hydrochloride is added nd mixed well.

The colour is allowed to develop for 30 min. before being ad colorimetrically, or absorptiometrically with a Wratten l filter. All estimates of sulphetrone are given in terms of e anhydrous compound. By collaboration with the Tinto-eter Ltd., a standard Lovibond colour disc is available for the rapid reading of blood and body-fluid estimates falling within the range of 0–9 mg. per 100 ml.

It has been shown (Brownlee et al. 1948) that the visible absorption spectra of the naphthyl-ethylene-diamine derivatives of diaminodiphenylsulphone and of sulphetrone are substantially different in preparations containing equivalent amounts of diaminodiphenyl-sulphone.

TOXICITY

The *acute toxicity* of sulphetrone when given by mouth experimentally to animals is so slight that it cannot be determined with any certainty (Brownlee et al. 1948). Comparison of blood levels at death between ordinary sulphonamides and sulphetrone show the latter to be many times less acutely toxic than sulphanilamide. In the dog acute toxic symptoms are absent with blood-sulphetrone levels as high as 160 mg. per 100 ml. This fact, together with the observation that conjugated derivatives cannot be detected in blood or urine, is a strong link in the chain of evidence that sulphetrone is not easily hydrolysed. Acute toxic effects are not observed in man.

Chronic Toxicity

Very large doses of sulphetrone can be given by mouth for a long time to mice and dogs without producing ill effects. In rabbits, however, a diet containing 4% sulphetrone causes blood changes: (1) a slight but continuous hæmolytic anæmia marked by a concurrent reticulocytosis; (2) a progressive anæmia due to lack of iron owing to competition for alimentary iron by sulphetrone, with which iron forms a non-absorbable complex, and which may be treated, or prevented, by the administration of iron parenterally or by mouth; and (3) an anæmia of slower development but precipitate onset which seems to be of nutritional origin, since it may be both prevented and cured by the simultaneous exhibition of brewers' yeast, and is probably caused by the limitation and alteration of the bacterial flora of the gut by sulphetrone (Brownlee and Tonkin 1941).

That an essentially similar condition develops in man is implicit in the cases reported by Madigan (1948), Anderson and Strachan (1948), and Clay and Clay (1948). The problem was studied intensively in 2 female patients presenting bilateral fibrocaseous disease, and both at first gravely ill. Sulphetrone-balance experiments were made for twelve months, involving daily estimates of blood-sulphetrone concentrations and of the amounts excreted in urine and fæces. Daily estimates were made of reticulocytes, red cells, white cells, and hæmoglobin concentrations; differential cell counts were also made. In all, estimates were made on 298 occasions.

The urine was examined for urobilin (Watson 1936) and abnormal pigment; total porphyrin estimates were made weekly on 24-hour specimens, subsequently to be abandoned because the estimates fell within normal limits. Reference is made below to a chemical study of metabolic products of sulphetrone. The *information* collected has allowed the study of several related problems also to be discussed. The figure summarises the typical response of a patient to sulphetrone by mouth; the dose was at first 3 g. daily (0·5 g. every four hours) and thereafter raised at seven-day intervals by increments of 1 g. until a therapeutic blood level of 7·5–10 mg. per 100 ml. was reached. The weekly estimates are means of seven daily observations. As with the rabbit, the residual effect is a hæmolytic anæmia, which stimulates reticulocytosis. The red cells were crenated, and hæmolysis in fragility tests was observed at 0·45 and increased at 0·48% NaCl.

In all the 94 cases examined no distinguishable effects on the numbers or distribution of white cells were

---

The development of sulphetrone is part of a programme of work on Antituberculous Compounds carried out by the Therapeutic Research Corporation of Great Britain.

student to become well grounded in the subject of his choice, and often determines the lines of his future career.

The tendency almost everywhere in America is to cut down didactic teaching, to assign personal instructors to small groups of students, and to use the seminar and the discussion rather than the lecture as the vehicle for teaching. Where students are certain to take an internship, the curriculum can be greatly improved. For example, in surgery it is possible to concentrate on major diagnostic problems and on minor surgery, and to omit details of operations and avoid excessive attendance in operating-theatres. Similarly, the load of teaching in the specialties can be reduced with advantage. At many schools physicians, while they are expected to have their own special interest, must take their full share in general teaching, whether they be hæmatologists, allergists, or cardiologists.

As a rule students pay in fees only one-fifth of the cost of their medical education. Often American schools spend on the student over $2000 a year in excess of fees received.

ADMINISTRATION

The success of a teaching hospital and medical school depends largely on the [illegible] tor who really directs and a dean who [illegible]. In the United States too many of the departmental chiefs, harassed and weighed down by their administrative burdens, are unable to deal properly with their fundamental duties of service to patient, teaching, and investigation. At Johns Hopkins, despite its well-developed tradition, a full-time dean is found to be necessary. Nevertheless, several outstanding American medical schools are run successfully by deans who take some share in teaching and an important part in research; and it seems essential that both dean and director should hold active teaching appointments, and that this principle should be extended to the assistant dean and deputy director. The dean need not, however, be chief of a professional department.

BUILDINGS

In the United States the trend is towards a simple type of functional building to house the medical school, so that as much money as possible should be reserved for salaries, equipment, and maintenance of the staff; good equipment takes precedence over beauty in buildings. The pace of development has made formerly outstanding buildings obsolete within a few years; and many planners now favour construction in which the plumbing and electric wires are placed, as far as possible, in outside walls, with the inner walls mere partitions no more than one brick thick, so that internal space can be reshuffled according to need. Rochester medical school exemplifies this type of design.

Schools are now commonly designed with an eye to compactness. Thus laboratory, ward, and teaching unit are in the closest physical proximity; within a single building one whole floor is devoted to each department; so a few steps or a few seconds in the lift separates one department from another. There is pronounced disinclination to separate the different departments in distinct institutes; the emphasis is on the unity of medicine and on easy passage between the clinical and preclinical departments. Indeed at some centres the medical school and hospital occupy contiguous structures, and each floor in the medical school houses a department appropriate to the adjacent hospital department on the same floor; thus the department of physiology and the department of internal medicine, with its wards, occupy the same floor of one large building and are divided simply by a door which joins rather than separates the two departments. This is a more powerful object-lesson to the student than a host of words on the value of the physiological approach in medicine. In some hospitals the appropriate outpatient department is incorporated on the same floor as the double units which have described; the outpatient department is then sepa by only a few feet from the wards; so the staff engaged inpatient treatment and teaching is immediately a sible to outpatients. The outpatient department sho be designed to incorporate preventive medical ideas practice.

PREVENTIVE MEDICINE

Many leaders in the medical field in the United States as elsewhere, are convinced that preventive medicine social medicine or community medicine (the best t is still a matter of dispute) will dominate medicine the future. The fact is that most medical students dominated by the dazzling influence of the professors internal medicine and surgery, with their emphasis diagnosis and curative treatment; and it is the ambition of most to set up in private practice (of high standard) the larger cities among the upper middle class. At pre this kind of practice seems to bring the richest financ and social rewards. The medical student looks upo preventive medicine as a kind of appendage, grafted o to the medical course proper, which he must suffer unt he passes the hurdle of his final examinations.

The attempt should be made to permeate the whole of the medical faculty with the preventive medicine idea. An integral part of the work of each existing division of medicine should be in the preventive field. The professor of preventive medicine should participate as an equal in medical ward rounds and indicate wherever appropriate what measures could have prevented the onset of disease and how to prevent recurrences. At Beth Israel Hospital Boston, there is a regular medical social ward round in which a senior resident, the intern, the head of th social-service department, medical students, and social workers participate.

The medical course from the very beginning shou be impregnated with the ideas and philosophy of pre tive and social medicine. The student should be brou up along these lines and not suddenly confronted w a special course which seems to be of no real interest many members of the medical faculty. The outpatie department should be linked up with the health centr and preventive medical teaching should be dominant the outpatient clinic. Field trips should form an integr part of the course. Stress should be laid also upon th family as a health unit.

All progressive departments of pædiatrics have lo been preventive medicine minded, but there is room f preventive medicine in other departments. Nutrition and psychiatry, bacteriology and tropical medicine spring immediately to mind. As Dr. Abel Wolman has put it: "The medical school should make the medical student feel that he is a junior fellow worker in a public health undertaking."

NURSING

It has been aptly said that the efficiency and knowledge of the American nurse are beyond dispute, but not beyo criticism. There is some truth in the statement th American nurses, after an expensive college educat take a long and arduous nursing degree course only become, on qualification, too superior to engage ordinary nursing procedures or work in the remoter smaller hospitals.

What I have seen in England, America, and Jerusale convinces me of the soundness of the plea of THE LANCE that all nurses should be given the same basic training of two years, and that all who pass such training succes fully should be given the designation of, say, qualifie nurse—"Q.N." *The more ambitious nurses and the mo* able nurses will then go on to take higher qualificatio —e.g., university degree, or State registration. This w attract into nursing, and keep in nursing, many girls wh are angels at the bedside but fools in chemistry.

lumn are the estimates of alkali reserve after seven ys' treatment; in the second, two months later. cluded within the second series are 3 patients who had ceived sulphetrone for seven days only. The estimates re made within 30 min. from freshly drawn blood ntrifuged under paraffin; the CO_2-capacity was termined by the volumetric method of Van Slyke. It ill be seen that there is no significant change in the O_2-combining capacity of the plasma after protracted eatment with sulphetrone.

Sulphetrone is well tolerated if the exhibition of the ug is gradual. Nevertheless, during this period of ljustment mild symptoms of toxicity are seen (Madigan 948)—slight nausea, mild headache, and difficulty in ading. These may be associated with the physiological ccommodation the patient is called on to make in alkali serve. The symptoms are relieved best by sodium icarbonate and not so well by lactate or citrate. The icarbonate ion (HCO_3)— may therefore be involved.

ABSORPTION AND EXCRETION

Experiments on mice and dogs in which single small or rge doses were given showed that, after a certain point reached, large increases in dose do not lead to either higher blood-sulphetrone level or increased absorption. imilar observations have been made with the more omplex sulphonamides at somewhat higher doses. The abbit is anomalous, for increase in dosage increases e absorption of sulphetrone and its concentration in the lood. In dogs the same total amount of sulphetrone iven in divided doses at intervals of a few hours led to higher blood-sulphetrone level than when given as a ingle dose. A similar effect was seen in man in ten xperiments restricted to 96 hours. The results of an xperiment on dogs in which sulphetrone was injected rst into the large and then into the small intestine, the leocæcal junction having been tied, support the view hat absorption is largely confined to the small intestine. t follows that optimal conditions of absorption are likely o follow uniformly divided doses.

ulphetrone and Metabolism Products in Urine and Fæces

Two female tuberculous patients given sulphetrone ere the subject of drug-balance experiments during a ontinuous period of twelve months. The intake of ulphetrone averaged 6·5 g. daily; the amounts of ulphetrone in urine and fæces were estimated. As already ndicated, the recovery of sulphetrone from urine was good, 90–95%, but only 75–82% could be obtained from fæces. Sulphetrone in the fæces does not indicate only the amounts which remain unabsorbed, since some secretion takes place into the bile and from the ileum. It is impossible to relate the amount of sulphetrone in the urine to the amount absorbed, for still other channels of excretion are open to it. After the initial period of adjustment, as little as two-fifths, and later as much as three-fifths, passed through the kidneys; as much as two-fifths and as little as a fifth was recovered from the fæces.

* Drug being withdrawn.

The urine of animals and man receiving sulphetrone contains a diazotisable substance which, when coupled with naphthyl-ethylenediamine, forms a dye with an absorption similar to that of sulphetrone. Heating with N/1 hydrochloric acid for 30 min. does not increase the amount of diazotisable material; thus there is probably no conjugation. The concentration of sulphetrone in urine is high—usually 10 to 20 times that in the blood.

The urine of patients treated with sulphetrone is a dark smoky-brown. The pigment may be separated chromatographically on a column of activated alumina (Brockmann: Messrs. Savory and Moore).

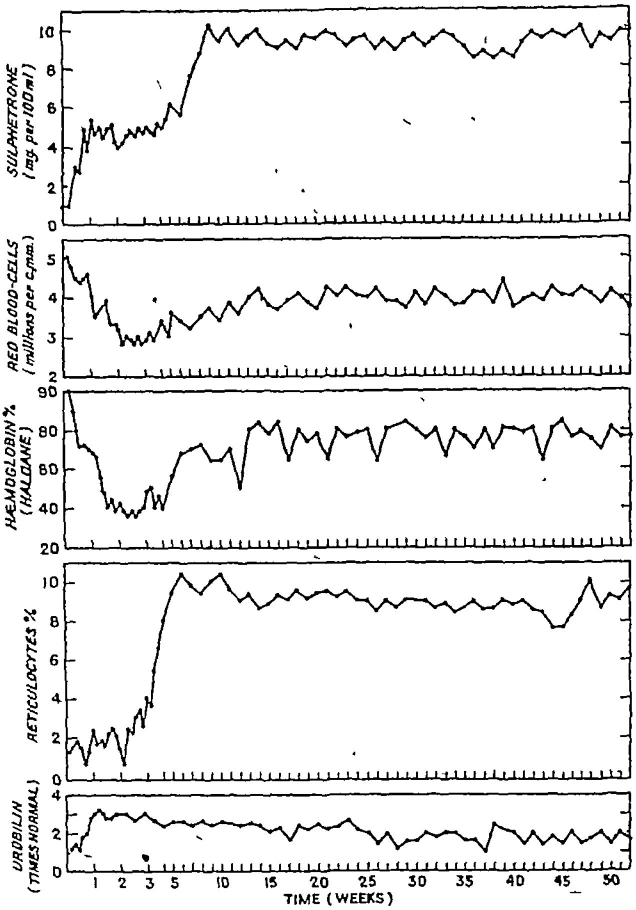
Most of this pigment separates as a dark brown 1½ in. band at the top. After washing with a similar volume of distilled water about 95–97% of the total diezotisable material passes through the column. The pigment may now be developed with 0·5% hydrochloric acid to give a blue-violet narrow band, followed closely by a mauve-pink broader band, with brown (bile) pigments left behind. The violet-blue pigment is soluble in 0·5% hydrochloric acid and, diazotised and coupled, appears to account for about 2% of the total sulphetrone in the urine. The mauve-pink solution in hydrochloric acid couples with difficulty; calculated as sulphetrone it appears to account for about 0·5% of the total.

It is interesting to speculate on the part played by these dyestuffs in the leaden-blue coloration of sulphetrone-treated patients excreting these dyes in their urine. The dyes appear to be condensation products of two or more molecules of sulphetrone, which, it will be recalled, loses alkali in the blood-stream, probably by just such a condensation procedure.

Renal Clearance

Sulphetrone is excreted by the kidney very fast. In rabbits the clearance was 58% of that of creatinine, or two or three times as fast as that of sulphanilamide, while in the dog the clearance was five times as fast as that of sulphanilamide (Brownlee et al. 1948).

The opportunity arose in a patient, repeatedly catheterised for the diagnosis of renal tuberculosis, to determine the clearance-rate of sulphetrone by direct comparison with sulphanilamide. Both drugs were given intravenously in a dose of



Typical response in man treated with sulphetrone 7·5 g. daily for 52 weeks, with increments of iron and fresh yeast to diet. Urobilin was estimated spectroscopically (Watson 1936).

observed. Consistent with the reticulocytosis observed in man there was an increase in the primitive rod cells of the bone-marrow.

The range within which the differential red bone-marrow counts fell in 11 tuberculous patients treated with sulphetrone was as follows:

		%			%
A	Polymorphs ..	3·5–34·4		Lymphocytes ..	3 8–22·8
	Metamyelocytes	0·0–33·4		Monocytes ..	0·4–10·8
	Myelocytes ..	1·8–11·5		Plasma cells ..	0·2– 2 0
	Promyelocytes	1·2– 4·0	B	Normoblasts ..	24·0–37·5
	Myeloblasts ..	1·2– 4·0		Erythroblasts ..	0·4– 1·0

The proportion of cells of the myeloid series (A) to nucleated red cells (B) is 1·24–2·5 to 1. This falls within the limits for normal marrow counts (Young and Osgood 1935). Estimates made on 2 of the 11 patients before treatment started gave ratios of 6·4 to 1 and 9·25 to 1.

Abnormal Blood Pigments

The blood of animals and man containing therapeutic concentrations of sulphetrone is usually dark brown, and the pigment is restricted to the red cells, even though sulphetrone is distributed within plasma and cells. Examined spectrometrically (Beckman) the blood may show no specific absorption characteristic of known abnormal blood pigments. In a proportion of cases, which may be as high as 20%, the specific absorptions of methæmoglobin (630 mμ) may be detected. Sulphæmoglobin (618 mμ) is absent. Methæmoglobin may be identified visibly by spectroscope but only in the strongest solutions of laked blood which will just transmit light. When it is present, calculations from the extraction coefficients of the wave-length corresponding to oxyhæmoglobin (540 mμ) and methæmoglobin (630 mμ) suggest that the amount present is about 4–12% of total hæmoglobin.

Blood containing concentrations of sulphetrone above 10 mg. per 100 ml. may contain additional abnormal blood pigments. For example, of 904 spectrometric estimates in this category 23 were abnormal: 18 contained sulphæmoglobin, and 5 appreciable amounts of methæmoglobin. In all other cases in which sulphæmoglobinæmia was observed in patients with blood-sulphetrone levels below 10 mg. per 100 ml. other drugs were implicated, phenacetin five times and methylacetanilide once. An additional abnormal pigment may be identified by a generalised absorption in the area 600–620 mμ. This may be a hæmoglobin-sulphetrone complex or a hæmoglobin-sulphetrone degradation product.

Oxygen-capacity of the Blood.—Whatever the precise nature of the abnormal pigment, its ultimate importance depends on whether or not there is variation in the oxygen-carrying capacity of the blood. A series of [illegible] patients, with blood-sulphetrone levels of 7·4–9 2 mg. per 100 ml., were observed for ten weeks in which five repeated estimates were made of the oxygen-capacity of blood, together with spectrometric estimates. The analyses were made in the constant-volume Van Slyke apparatus. In this small series the estimates of oxygen capacity were lower than normal in 5 cases, though associated with the presence of methæmoglobin in only 2 (table I). The rate of oxygen (air) uptake was always slower than in normal blood.

Blue Coloration of Patients.—Associated with these facts is the clinical observation that many patients treated with sulphetrone show a leaden-blue coloration of skin and mucosæ. The tint and distribution of the colour are reminiscent of sulphæmoglobinæmia, which, as noted above, is absent. The intensity of pigmentation is not related to the blood-sulphetrone level but is greater during the early period of adjustment. It is less obvious in the young, and most pronounced in those with l vital capacity. There is at the same time a quantity violet-blue dye in the urine. Clinically the condition do not contra-indicate the exhibition of sulphetrone.

Specific Toxic Effects

Sulphetrone shares with the sulphonamides the property of causing hyperæmia and hyperplasia of the thyroid gland in laboratory animals. The hyperpl is thought to result from diminished synthesis of thyroid hormone. The tests showed sulphetrone to be the le and sulphaguanidine the most toxic, with sulphadiazine intermediate. The effect has not been observed in man.

Effect on Alkali Reserve

The lack of acute toxicity and the low chronic toxicity, with freedom from the characteristic nervous sequelæ seen in experiments on animals after the administration of diaminodiphenylsulphone, make it clear that sulphetrone is not degraded to any extent to diaminodiphenylsulphone in the body.

A point which must not be overlooked is the possible hydrolysis of one or more of the four sulphonated side-chains and animal experiments were made to study this p (Brownlee et al. 1948). Simple hydrolysis with liberation sodium acid sulphate appeared likely, but experiments rabbits given sulphetrone by mouth and parenterally, and dogs given sulphetrone parenterally, showed increased in the blood. Comparison with the effects of administe alkali parenterally showed the increase in alkali reserve to consistent with the liberation of one molecule of sodi hydroxide from each molecule of sulphetrone. This w involve the production of a condensation product of sulphetrone, and there is experimental evidence in man pointing the excretion of a coloured complex of this kind in the urin

It is significant that tests made on rabbits given sulphetrone for long periods showed the animals to be capable of establishing an equilibrium in plasma-alkali balance.

The alkali reserves of untreated and treated tuberculous patients are compared in table II. In the fir

CHEMOTHERAPY OF PULMONARY TUBERCULOSIS WITH SULPHETRONE

rom Knightswood Infectious Diseases Hospital, Glasgow

THIS report records the results of a trial of 'Sulphe-ne' mainly in pulmonary tuberculosis. Though the al has been proceeding for three years, progress has n slow partly because of the need to ascertain the icity of sulphetrone and partly because of the difficulty ountered in assessing results.

Knightswood Hospital receives notified cases of lmonary tuberculosis from all parts of the city of asgow. There is some selection before admission, that a high proportion of the patients have fairly vanced disease and are regarded as unsuitable for tificial pneumothorax or other active treatment.

TABLE I—RESULTS OF TREATMENT WITH SULPHETRONE

	Totals ..	12	40	12	10	26	100

uch cases seemed most suitable for the trial of a new rug because: (I) they would be likely to show any toxic ffects more readily; and (2) chemotherapy would not e influenced by other methods of treatment. From ich cases patients were selected for study whose eneral condition, after careful review, was regarded as tisfactory.

There were three main stages in the trial. At first e drug was given to patients with tuberculous eningitis to gain experience in its use. Since all such ses pursue a uniformly fatal course, it was thought stifiable to adopt a varied dosage so as to observe the stribution of sulphetrone in the body and the toxic fects to which it might give rise. Thereafter our st patients with pulmonary tuberculosis were treated. t first we selected patients with advanced disease d a poor prognosis. Later we began to select patients ith less advanced lung disease, including several ildren. Because of the care required in clinical anagement it was never possible to have large numbers nder treatment at the same time.

GENERAL MANAGEMENT AND CLINICAL CONTROL

All patients received the same basal treatment—etetic and symptomatic. To begin with, rest in bed as enforced during sulphetrone therapy, but gradually this rule was relaxed and patients were allowed up on the usual indications. Some have continued treatment as outpatients.

To estimate the progress of the tuberculosis the following examinations were carried out regularly: radiography, examination of sputum for *M. tuberculosis*, measurement of erythrocyte-sedimentation rate (E.S.R.), weight, and the usual physical examination.

Before the start of treatment each patient had a blood examination which included estimation of the hæmoglobin, total red-cell and white-cell counts, and a differential white-cell count. The hæmoglobin and the red-cell count were repeated frequently (at least once a week), since it was believed that the most serious toxic effect was exerted on the red cells. Continuation of treatment and dosage largely depended on the results of these examinations.

Sulphetrone was given by mouth four-hourly in tablets each containing 0·5 g. When treatment was started, a daily dose of 3 g. was usually prescribed, and this was continued for at least a week. Thereafter the daily dose was gradually increased in an attempt to secure blood-sulphetrone levels of 5–8 mg. per 100 ml. In most adults a daily dose of about 9 g. was sufficient, but occasionally doses of 12–15 g. a day were given. In the early stages of the experiment the blood-sulphetrone level was estimated every second day, but latterly a weekly estimation was considered sufficient.

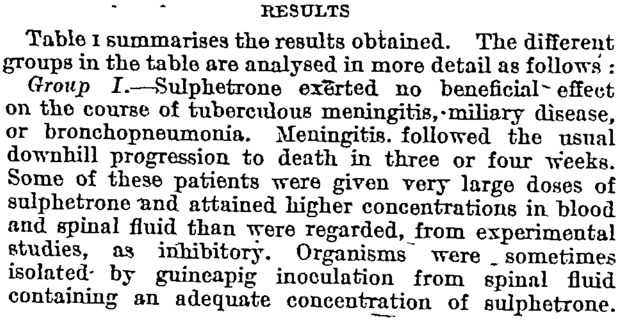
Sulphetrone is exceedingly soluble and is more rapidly eliminated from the kidneys than are the sulphonamides. To secure satisfactory blood-sulphetrone levels it was found necessary to limit the fluid intake to three pints a day. Alkali was given with each dose and, to prevent anæmia, most of the patients received iron.

As our knowledge of the drug and its effects increased, only one major change was made. At first, because of the fear of toxic reactions, we had limited the period of treatment to six weeks; after a rest from sulphetrone for a similar period treatment was continued. The duration of each course of treatment became gradually longer as we saw the need for sustained therapy; until latterly we tried to keep the patient continuously on sulphetrone.

RESULTS

Table I summarises the results obtained. The different groups in the table are analysed in more detail as follows:

Group I.—Sulphetrone exerted no beneficial effect on the course of tuberculous meningitis, miliary disease, or bronchopneumonia. Meningitis followed the usual downhill progression to death in three or four weeks. Some of these patients were given very large doses of sulphetrone and attained higher concentrations in blood and spinal fluid than were regarded, from experimental studies, as inhibitory. Organisms were sometimes isolated by guineapig inoculation from spinal fluid containing an adequate concentration of sulphetrone.



(a) (b)

Fig. 1—Bilateral pulmonary tuberculosis with left pleural effusion (case 6): (a) before treatment; (b) after treatment with sulphetrone.

0·05 g. per kg. and five estimates were made at intervals of 30 min. The mean clearance for sulphanilamide ± S.D. was 12·2±2·4, whereas for sulphetrone, tested after an interval of eight days, it was 62·1±11·3.

It seems that, in man, tubular resorption of sulphetrone is small, and that the rate of clearance is about four times as fast as with sulphanilamide.

TABLE III—PENETRATION OF SULPHETRONE INTO VARIOUS TISSUES IN MAN, EXPRESSED AS MG. PER 100 ML. OF BLOOD OR OTHER FLUID AND AS MG. PER 100 G. OF TISSUE.

DISTRIBUTION OF SULPHETRONE IN TISSUE

Sulphetrone rapidly penetrates all tissues except brain, but it appears in cerebrospinal fluid more slowly than do sulphonamides. The tissues of animals show similar concentrations whether the sulphetrone is given in a sufficient dose intravenously or by mouth over a period of ten weeks (Brownlee et al. 1948). In experiments on animals concentrations of sulphetrone in liver, kidney, and spleen are always greater than in plasma; the same is true for man (table III). The relation between absorbed sulphetrone, sulphetrone in transport, and sulphetrone in kidney clearance does not seem to be a simple one, and conditions other than the concentration of sulphetrone in the plasma appear to coöperate in determining the amount in the tissues. Plasma-sulphetrone levels obtained in nephrectomised rabbits are many times those seen in normal rabbits, and many times the level attained in other tissues. The concentrations in the bile of both normal and nephrectomised animals are very high; in the normal animal the concentration in bile is about twelve times the plasma value and must be considered to be sulphetrone in transport, so that biliary excretion makes a significant contribution to the clearance of the drug.

The study of the distribution of sulphetrone in the tissues in man has necessarily been confined to necropsy specimens. Cases 1, 2, and 3 of table III show the distribution of sulphetrone in different tissues when the blood-sulphetrone was at a therapeutic level, at death after tuberculous meningitis (2 cases) and hæmoptysis (1 case). Cases 4 and 5 show the distribution of sulphetrone in different tissues after excessively high and long-maintained blood-sulphetrone levels caused by constipation allowing sulphetrone to accumulate in the small intestine. In both cases the blood-levels were maintained at 17·5 mg. per 100 ml. for more than five days. D from anoxia followed from the inability of the red to transport oxygen.

SUMMARY

The chemical and physical properties of sulphet and its estimation in body fluids are described.

The acute toxicity of sulphetrone in experimenta animals is very slight. No acute toxic effects have observed in man.

The chronic hæmatotoxic effects in rabbits and in ma include a hæmolytic anæmia, an anæmia of iron lack, a an anæmia of nutritional origin.

Sulphetrone has a goitrogenic effect similar to that o sulphonamides, but this is only slight in experimenta animals and has not been observed in patients receivin the drug.

Sulphetrone, given by mouth or parenterally raises th alkali reserve of the plasma of rabbit and dog. Th probable mechanism is discussed. Given over a lon period it brings about some tolerance. It is thought th the period of adjustment seen during the first three wee of sulphetrone therapy is associated with adjustments o alkali reserve. The minor discomforts encountered durin this period are relieved by bicarbonate, but not so wel by other alkalis.

Though very soluble in water, sulphetrone is slowly absorbed from the intestinal tract—most from the small intestine, little from the large.

Sulphetrone is cleared by the kidney very quickly, and fluid must be limited to maintain blood-sulphetrone concentrations; there is also a substantial excretion into the bile and to a lesser extent into the ileum. The drug is not conjugated; so there is no danger of crystaluria.

Sulphetrone penetrates all tissues, except brain, ver rapidly. It passes into the cerebrospinal fluid mor slowly than do sulphonamides.

Thanks are due to Dr. A. I. Ross, of Farnborough Co Hospital, who was responsible for the bone-marrow biop Dr. T. Anderson and Dr. D. G. Madigan for permis to draw on their clinical necropsy findings; Dr. E. I. S for some of the oxygen-capacity and spectrometric observa- tions; Dr. C. L. Oakley for the histological reports.

“. . . If the availability of medical care were to raise th level of health in industry, and if the assurance of unem ployment pay, old age pensions and funeral expenses lift such a load of worry from our minds that we slept bett and tackled our work with more nervous vitality, then o production would go up. If it went up sufficiently, we m carry all the extra clerks, extra doctors, and other wo required for social security and dance under the load, n while enriching ourselves more than ever in other ways. A very different result is also possible: for a population which everyone felt certain that he could not sink m below a tolerable minimum of comfort and in which th higher prizes of property and independence had been curtailed in size and number, might see not more but less reason t devote itself to productive effort. . . . Now that we ar embarked on the scheme, we must work and hope for th former result, but had better be on our guard against th latter. In the end, it will prove to be a social advan only if it marks a turning-point in our conception of societ and social purpose.—*New English Weekly*, July 15, p. 1

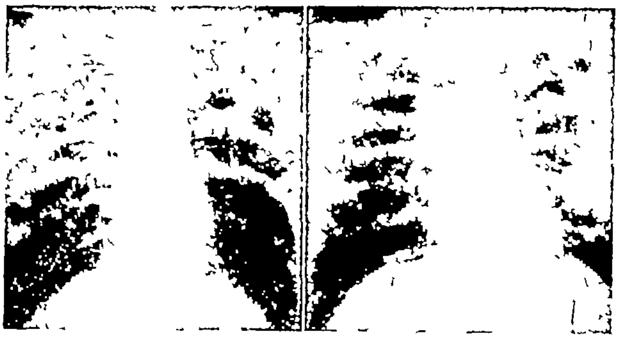

Fig. 2—Bilateral pulmonary tuberculosis (case 9): (a) before treatment; (b) after treatment with sulphetrone.

Similarly, in what might be termed acute tuberculosis there was no apparent intermission in the progression of the disease.

Group II.—All of the patients included in this group showed extensive tuberculosis of both lungs. There was usually considerable cavitation. The prognosis from the beginning was bad, and it was unlikely that any form of treatment would be beneficial. This part of the experiment was to a large extent planned to show that even patients with advanced disease and in poor condition could tolerate sulphetrone reasonably well, provided adequate precautions were taken. Because of the toxæmia already present, however, the chemotherapy of such patients was more difficult to control and, in some, sulphetrone was not well tolerated. A hæmoptysis, for example, always caused anxiety, since the sudden depletion of hæmoglobin, added to anæmia due to sulphetrone, might produce dangerously low hæmoglobin levels. Only one of these patients showed any benefit from the treatment. The patient, a female aged 23, had extensive disease throughout the left lung with cavitation, and active infiltrative disease in the upper third of the right lung. Under sulphetrone therapy there was considerable improvement in the lesion on the right side, which was eventually considered to be arrested. A thoracoplasty has now been performed on the left side, and the result at present is excellent.

Group III.—This group comprises patients with pulmonary tuberculosis whose prognosis was initially more hopeful, though in some of them the disease was fairly extensive. In most of them both lungs were affected, and in some there was radiological evidence of cavitation. Some of them were chosen for study with the limited objective of checking a more recent spread into one lung from a more chronic disease in the other. There were 36 patients in this group, and 23 of these showed improvement after a period of sulphetrone therapy. Relevant details of these 23 patients are given in table II, which shows that many of the patients were under observation for a short period before beg treatment, and that in some there was no improve during this time. All received adequate and pro treatment, and in 8 of the cases radiological and ba logical examination supported a belief that the tu culosis had been arrested. In 2 other patients (ca and 16) the disease in one lung was arrested and a tho plasty was performed on the opposite side. They in excellent condition. The radiograms before and treatment from 3 of these patients (cases 6, 9, and are shown in figs. 1–3.

Group IV.—The 19 patients included in this were all under 15 years of age. They were distrib in age-groups as follows: 4 aged 1–2 yr. (1 did improve); 2 aged 2–3 yr.; 5 aged 3–5 yr., 5 5–10 yr. (1 did not improve and 1 improved slightly and 3 aged 10–15 yr. (1 did not improve). There many different forms of tuberculosis. The diagnosis based on radiological and clinical findings, and many of these children, before treatment start *M. tuberculosis* was found in stomach washings. Opin is divided on the question of prognosis at this period life, but it is generally agreed that age is of prima importance. No patient in this group was discharg from hospital unless the radiological picture was norm and three consecutive samples of fasting stomach ju

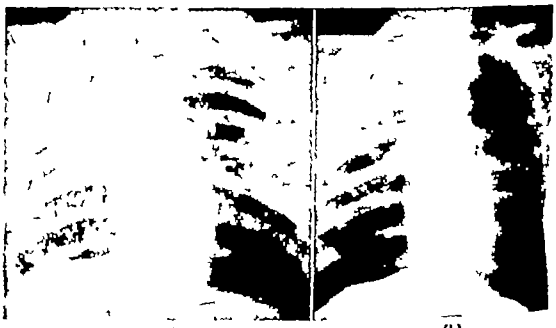

Fig. 3—Bilateral pulmonary tuberculosis (case 10): (a) before treatm (b) after treatment with sulphetrone.

did not show *M. tuberculosis* on inoculation into gui pigs. Of these 19 patients 15 were discharged and m therefore be regarded as having had their tubercul arrested. They have been followed up for four eighteen months since discharge, and all have remai healthy. The duration of stay in hospital was as follow

No. of days in hospital	100–199	200–299	300–399	400–499	500
No. of children	2	5	6	1	1

Average stay in hospital: 302 days

Radiograms from one of these patients are shown fig. 4. This case is of interest because, after a p liminary period of observation. the condition defin deteriorated (fig. 4a a After a period of su trone therapy lastin weeks he was disch with the tubercu arrested (fig. 4c). A ne re-examination show that the condition was quiescent.

Group V.—The patients in this gr were chosen for st because they all definite evidence of tu culous pleurisy w effusion. Stomach wash

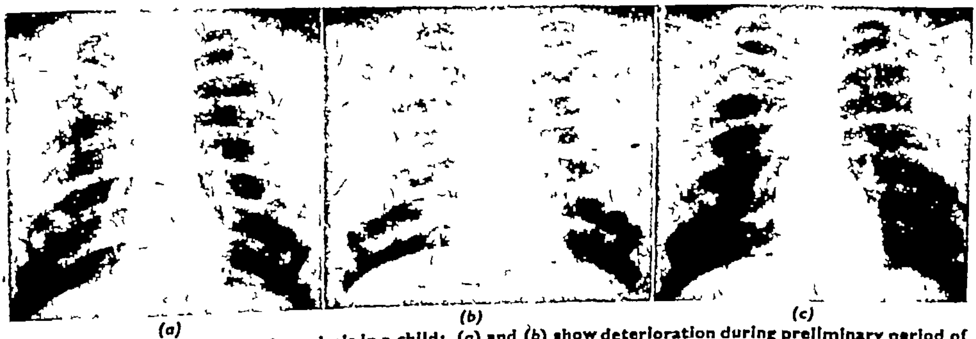

Fig. 4—Bilateral pulmonary tuberculosis in a child: (a) and (b) show deterioration during preliminary period of observation; (c) disease arrested after 45 weeks' sulphetrone therapy.

ɔn under observation for three years; thoracoplasty ʒ been done on the side with the extensive disease, d the lesion on the opposite side remains inactive.

In some cases, however, there has been no improve- ɔnt under sulphetrone therapy, although our experience ggested that the patients would benefit from treat- ɔnt. In some of these we cannot explain the failure.

The absence of controls may be regarded as a serious ılt in this trial. But it would have been at least very ficult to obtain untreated patients equivalent in all pects to those treated. The amount of care required clinical management, especially at the beginning, ıde it impossible to conduct a trial along the usual es of treating alternate cases. In tuberculosis, leed, such a trial would have to include a very large mber of patients if all the factors liable to affect the urse of the disease were to be balanced in the two oups.

Our results show that chemotherapy with sulphetrone ın be safely applied to patients with pulmonary tuber- losis, and can exert a favourable effect on certain pes of the disease. The results give some basis for e belief that control of the disease by chemical means possible.

We wish to thank Dr. R. D. Stuart, city bacteriologist, asgow, who carried out the examinations on samples of stric washings by guineapig inoculation; the late Dr. F. L. nderson, consultant radiologist, Glasgow Public Health partment, for assistance in reading the radiograms; Dr. F. escott and Dr. G. Brownlee for advice and criticism; and ssrs. Burroughs Wellcome & Co. Ltd., for supplies of lphetrone.

OBSTETRICAL EVALUATION OF THE PUBIC ARCH

A CLINICAL METHOD

W. I. C. Morris*
M.B. Edin., F.R.C.S.E., M.R.C.O.G.
SENIOR LECTURER, DEPARTMENT OF OBSTETRICS AND GYNÆCOLOGY, UNIVERSITY OF EDINBURGH

The use of radiology in obstetrics has led to increasing tention being paid to the shape and size of the pelvic tlet in relationship to dystocia. Various expedients ve been devised for clinical measurement of the outlet, which the best known is that proposed by Williams 909), following the technique originally introduced by ien (1896), and described in all standard textbooks. is involves the simultaneous measurement of (*a*) a line ning the two ischial tuberosities, and (*b*) the distance tween the midpoint of this line and the sacrococcygeal nt—i.e., (*a*) the intertuberischial and (*b*) the posterior gittal diameters.

The practical difficulties in making these measurements e considerable. I have maintained (Morris 1947) that, view of these difficulties, it is justifiable in clinical tlet pelvimetry to concentrate on one measurement ich can be made with reasonable accuracy—i.e., the ortest distance between the symphysis pubis and the ral tip—plus an approximate estimate of the distance ween the ischial spines and of the amplitude of the bic arch. It is in connexion with the amplitude of e pubic arch that suggestions are put forward here.

It is difficult to devise a satisfactory method of measur- the pubic arch, whether in the dried pelvis, clinically, radiologically. Moir (1946) has proposed the radiological method of superimposing a transparent model of a fœtal head on the X-ray image of the bones, and similar techniques have been described independently by Allen (1947) and Morris (1947). I use a circular transparency with a diameter of 9·3 cm., corresponding to the biparietal diameter of the fœtal head. It is possible by this means to estimate the degree of probable bony obstruction by noting the size of the gap between the disc and the apex of the pubic arch (figs. 1 and 2). An average pubic arch may show a gap of 1 cm., but anything greater than this is regarded as indicating a narrow arch.

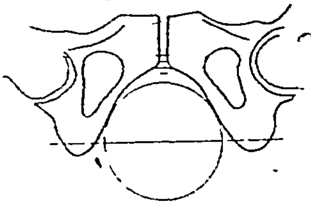

Fig. 1—Average pubic arch.

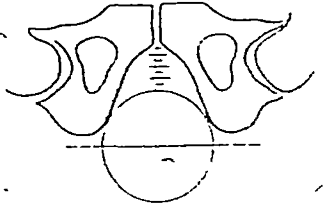

Fig. 2—Narrow pubic arch.

It occurred to me that this method might be adapted to the clinical determination of the size of the pubic hiatus, and trials were undertaken with a disc 8 cm. in diameter, a measurement somewhat arbitrarily chosen, since it was intended to apply the instrument to the external aspect of the pubic arch, and it was obviously necessary to allow for invaginated soft tissues intervening on each side between the edge of the disc and the conjoint rami.

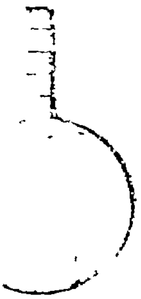

Fig. 3—Phosphor-bronze disc with centimetre scale attached, for measuring pubic arch.

CONSTRUCTION OF DISC

Originally a wooden disc was constructed, having a diameter of 8 cm., with one surface completely flat and the other very slightly convex, the thickness of the disc being about 2 mm. at its periphery and 7 mm. in the centre. A short strip of wood bearing a centimetre scale

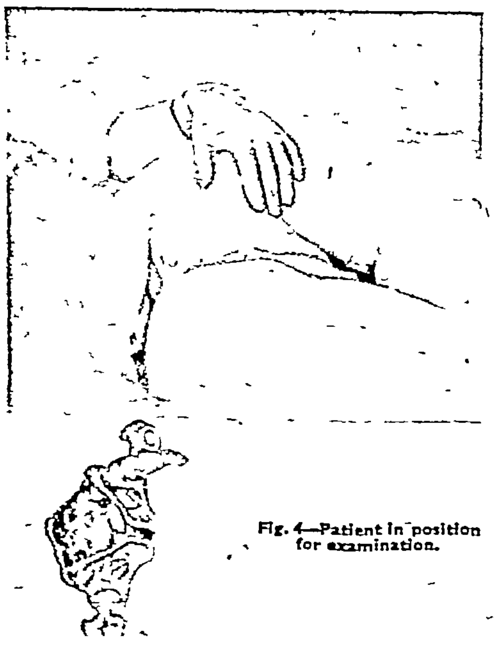

Fig. 4—Patient in position for examination.

---

* In receipt of a grant from the Medical Research

were examined by guineapig inoculation in 9, and 7 proved positive. In 4 patients obvious intrapulmonary disease was also present. The only factors which can be adduced as possible evidence of satisfactory treatment are the rapidity of discharge from hospital and the permanence of cure. The average duration of stay in hospital of those who were discharged was 202 days. The cases have been reviewed from five to thirty months after discharge, and none of the cases classified as cured has shown a breakdown.

Groups VI and VII.—The cases of genito-urinary and skin tuberculosis are too few to be analysed. We were impressed with the rapidity and completeness of the cure in cutaneous tuberculosis.

TOXIC EFFECTS

Anæmia.—We have already mentioned that the most common toxic effect was on the red blood-cells resulting in anæmia. All patients showed a fall of about 2 g. per 100 ml. in the hæmoglobin concentration during the first five or six weeks of treatment with sulphetrone. The cause of this fall has been investigated by one of us (S. J. S.) and will be the subject of a later report. The fall was less abrupt when the patient was started with a low dosage of sulphetrone and the daily amount was slowly increased. After the initial drop the level either rose very slightly or remained steady at the low level. As a rule throughout treatment the hæmoglobin was fairly steady at 9–11 g. per 100 ml. The fall in hæmoglobin was accompanied by a parallel decrease in the red-cell count. No change was observed in the white-cell count of any of the patients.

Cyanosis was also evident in all patients. The colour varied from a rather intense purple to a paler lilac or mauve. It reminded us of the intense cyanosis due to sulphæmoglobinæmia occasionally seen with sulphonamide therapy, but spectroscopic examination of the blood showed that this was not present. Patients varied in the extent to which they became cyanosed, but in general the degree ran parallel with the blood-sulphetrone level, deepening as the level rose. The combination of cyanosis and pallor gave the patients a rather striking and ill appearance. When treatment was stopped the cyanosis was slow in disappearing and usually remained evident for seven to fourteen days.

Headache, Nausea, and Vomiting.—These were the commonest subjective complaints affecting about half the patients. Sulphetrone has an unpleasant soapy taste, and some patients found it difficult to take. That this did not constitute an insuperable difficulty is shown by the fact that some patients have been continuously on sulphetrone for over a year. In one respect, however, these effects were important. As a rule patients did not eat so well and either gained no weight or lost a little while on sulphetrone.

Other Effects.—In 10 cases the patients developed a sensitisation rash similar to that occasionally seen with sulphonamide therapy. In 6 of them the rash was accompanied by drug fever. In some of these cases treatment was continued with due care and the rash gradually disappeared. One other patient developed an exfoliative dermatitis accompanied by an acute hæmolytic anæmia and died. Occasional effects observed temporarily were itching of the skin, tingling of the fingers, and blurring of vision. As is the case with sulphonamides, the children tolerated sulphetrone very well and gave rise to least anxiety.

In view of the occasional severity of the toxic signs patients under treatment require careful and continuous supervision. The daily dose of sulphetrone should always be started at a low level (3 g. a day or less) and increased gradually week by week. At all stages of treatment close attention must be paid to two examinations: the hæmoglobin must not fall below 7 g. per 100 ml.; and the blood-sulphetrone level must exceed 8–9 mg. per 100 ml. We found toxic eff much less likely in patients gradually accustomed the drug. We do not wish, however, to exaggerate incidence of toxic reactions, for our experience indic that, given in the way described, sulphetrone is unduly dangerous but merely demands reason caution.

DISCUSSION

In considering the chemotherapy of tubercul some general conclusions from the sulphonamide ther of acute bacterial infections are worth notice, they may have a more general application.

(1) Sulphonamides are most effective when the numb infecting organisms is small (Colebrook et al. 1936). T sulphones might be expected to show a similar prefere In many cases, particularly of extensive tuberculosis, number of bacteria present may be very large and m therefore hinder effective action.

(2) Effective sulphonamide therapy depends mainly on a b teriostatic action; the host is left to overcome the infective ag himself. Even in acute bacterial infections cases are encou tered in which, despite adequate chemotherapy, the results less successful. It has been argued that this poorer respo may be due to a poverty in the host's defensive mechanis (Anderson 1943, Department of Health, Scotland, 194 In acute tuberculosis it is not so much the increased virulen of the bacterium that explains the rapid course of the disease as the breakdown of the host's resistance, and in such cases his sulphone therapy may be expected to fail. The uniformly bad results obtained in group I do not seem to us unexpected and may well be explained in this way.

(3) It is a general clinical finding that the presence of pus invalidates treatment with sulphonamides. It has bee shown that pus and necrotic tissues contain anti-sulphonami substances which counteract effective action (MacLeod 19 It seems probable that the pus of tuberculous cavities cont similar substances capable of inhibiting the bacterio effect of the sulphones. Our own clinical observations in present study support this view, for cases with cavitat disease have not, on the whole, responded to treatm The patients in group III who responded most satisfact were those in whom cavitation was not obvious.

(4) Chemotherapy cannot repair damaged lung ti Where a profound pathological change has already ta place the most that can be done is to prevent further exten of the disease.

Tuberculosis thus presents a problem in chemothera which is not yet completely soluble. For in many ca even though the drug inhibits the parasite successfu and enables the patient to halt new invasion and perha to heal recent disease, the patient is often left with lung so seriously damaged from old disease that healing beyond his capacity. When the lesion is unilateral surgery may achieve collapse of the damaged lung an thus encourage healing. But with bilateral disea this may not be practicable and the continued presen of active chronic disease will leave the patient liable hæmorrhage and bronchogenic spread. In such ca sulphetrone therapy may sometimes be justified the limited objective of arresting disease in one (where it is recent and infiltrative) to permit surg attack on the more extensively diseased opposite In 4 of our cases, by bringing more recent disease o opposite side under control, sulphetrone rendered patient suitable for thoracoplasty. But as a rule regard cases with extensive fibrocaseous tuberculosis unsuitable for chemotherapy.

The type of lesion which seems to us most likely benefit from such treatment is the early infiltra lesion. Our results in group III are, we believe, improvement on what could have been expected fr ordinary rest in bed. Nearly all of these patients w regarded as unsuitable for more active treatment. T tuberculosis was apparently arrested in 8 of the patient and they have so far remained healthy. One has n

;. 7 shows the findings in respect of an ample arch. ;. 8 shows those in a patient with a narrow arch.

RADIOLOGICAL CHECK

At the beginning of the investigation 20 patients were amined both clinically and radiologically, and the easurements were found to correspond extremely sely. In no case was the divergence between radiogical and clinical measurements greater than 0·5 cm.; d, when the arches were divided into two groups fined as narrow (gap more than 1 cm.) and ample ip 1 cm. or less), the correspondence was exact. larger series is now being accumulated.

CONCLUSIONS

With the instrument and technique described it is ssible to detect narrowing of the pubic arch and ughly to assess its degree. But it is not suggested at such a rough method of examination is enough to ime any precise prognosis of the outcome of labour, iich may or may not be influenced by narrowing of e pubic arch, depending on various factors discussed sewhere (Morris 1947). However, this is a much more curate method of evaluating the obstetrical calibre of e pubic arch than any of the standard subjective timations depending simply on palpation, and at the ry least it enables the obstetrician to detect the cases which the pubic arch requires radiological investigation.

I am indebted to Messrs. Archibald Young and Co. for nstructing the metal gauge

THE demonstration of tubercle bacilli in discharges om the respiratory tract is the most convincing evidence pulmonary tuberculosis and a valuable index of ive disease. When such material is spontaneously pectorated, microscopical and cultural examination is ually adequate for diagnosis. In certain types of se, however, sputum is scanty or absent or, if present, not available for examination because it has been allowed.

Several methods of isolating the tubercle bacillus in e absence of expectoration have been devised. Cultural amination of fæces, of material coughed on to a ryngeal mirror, of laryngeal swabs, of cough ates, and bronchial lavage have been tried but have t been generally adopted in routine practice. Examition of the contents of the fasting stomach is now garded as the most effective and reliable means of olating tubercle bacilli in patients who do not expecrate. The results obtained by this method compare vourably with those of sputum culture (Robinson and unn 1943, Webster 1943), and the method is of ndoubted value in diagnosis and as a test of quiescence sputum-free and sputum-negative patients. The collection of stomach contents, however, is difficult in outpatients; hence a simpler method of obtaining material for bacteriological examination from such outpatients and from hospital inpatients requiring repeated examinations is needed. We have consequently investigated the value of laryngeal swabs for this purpose.

In 1905 Blume first used the laryngeal swab as an aid to diagnosis in human tuberculosis. He limited his examination to direct microscopy of smears made from the charged swabs. It was not until 1931 that culture of the swab on egg media was tried. Grass (1931) took swabs from 22 cases of pulmonary tuberculosis and isolated tubercle bacilli on culture of 11 of them; only 4 of these swabs were positive on direct microscopy. Dornickx (1937), Bezançon et al. (1937), and Böhm and Ekstein (1938), using Grass's technique or some modification of it, obtained satisfactory results in patients who did not expectorate. Thus, of 271 sanatorium patients with no sputum or with negative sputum, Böhm and Ekstein (1938) obtained positive culture of laryngeal swabs from 56 patients. The use of the laryngeal swab in this country has been reported by Nassau (1941) and Clark et al. (1945). Nassau obtained a positive result in 44% of 273 sanatorium patients who did not expectorate. The technique used in our investigation was a modification of Nassau's method.

METHOD

The swab consists of a piece of nickel or 'Nichrome' wire 9 in. long and $^{1}/_{16}$ in. in diameter, bent at an angle of 120° an inch and a half from the end. Cotton-wool is wrapped round this end of the wire, which has been flattened and spirally twisted to hold the cotton-wool firmly. Each swab is placed in a boiling-tube (7 × 1 in.) the open end of which is plugged with cotton-wool. The tubes with swabs in position are sterilised in the autoclave. Immediately before use the swab is moistened with sterile distilled water.

The swab may be passed into the larynx either with the guidance of a laryngeal mirror, or blindly. For both methods the patient is seated and supplied with a piece of gauze with which to hold his tongue fully protruded. The operator, if using a mirror, sits opposite the patient and with the aid of the mirror guides the tip of the swab over the epiglottis into the larynx. If working blindly, the operator stands at the side of the patient and passes the swab through the mouth backwards and downwards strictly in the midline; the manœuvre is facilitated by asking the patient to take panting breaths. Reflex cough usually develops as the swab enters the larynx, and absence of cough suggests that the swab has not entered the larynx. In the present series two swabs were taken from each patient.

In the laboratory sufficient 10% H_2SO_4 (v/v) is added to the boiling-tube to cover the cotton-wool on the swab. After 5 min. in acid the swab is removed, excess of fluid is expressed on the side of the tube, and the swab is transferred for a further 5 min. to a second boiling-tube containing a similar amount of 2% NaOH. The swab is again drained of excess fluid and is rubbed over the surface of a slope of Löwenstein-Jensen medium. The inoculated medium is incubated at 37°C and examined at weekly intervals. A positive report may be given when characteristic growth of tubercle bacilli is recognised. This may take from two to six weeks' incubation. Cultures which remain negative at the end of six weeks are discarded.

It has been our practice to carry out confirmatory tests on all tubes showing growth, to exclude saprophytic mycobacteria and non-acid-fast contaminants. A film of the growth is stained by the Ziehl-Neelsen technique and, if acid-fast bacilli are present, is subcultured on Löwenstein-Jensen and nutrient-agar slopes, which are incubated at 37°C and room temperature. If the morphological and/or cultural characters of an acid-fast organism are in any way atypical of *M. tuberculosis*, or if the bacteriological result is at variance with clinical findings, a guineapig-virulence test is carried out. All acid-fast organisms thus tested have proved to be human type *M. tuberculosis* and pathogenic to guineapigs. Contamination with non-acid-fast organisms (diphtheroids, coliforms, and moulds) took place in less than 2% of all cultures.

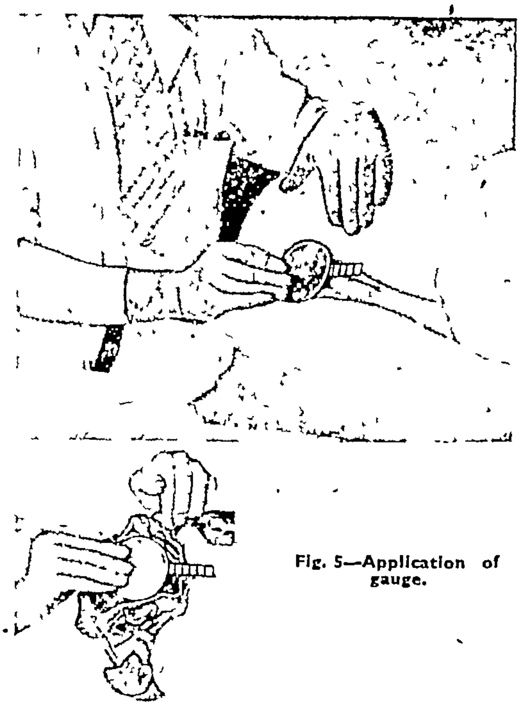

Fig. 5—Application of gauge.

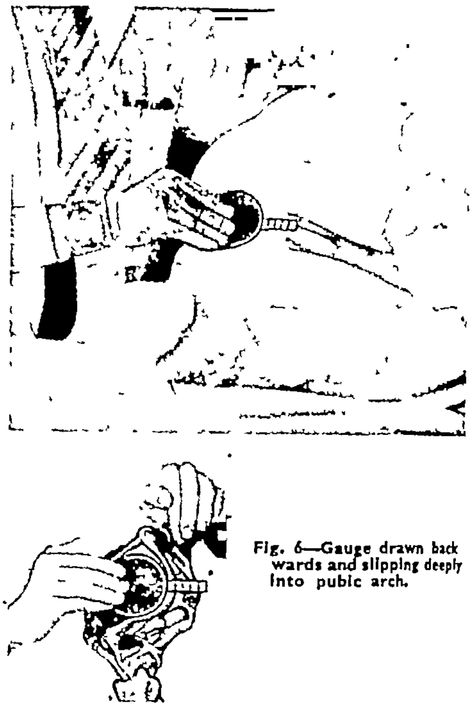

Fig. 6—Gauge drawn backwards and slipping deeply into pubic arch.

was glued into a slot on the flat surface of the disc, so as to protrude from the circumference of the disc at one side.

Later, a similar disc (fig. 3) was cast in phosphor-bronze, with a brass centimetre scale attached. This has been satisfactory in practice and, having the advantage of being readily sterilisable, it has taken the place of the prototype.

METHOD OF USE

The patient is placed in the left lateral position with the thighs hyperflexed, the right thigh being slightly abducted and held steady by the patient herself or by an assistant (fig. 4).

The convex surface of the disc is applied over the vulva (fig. 5), with the scale directed forward in the midline. Gentle pressure being made against the vulva, the disc is drawn backwards, until it slips between the conjoint rami, when it instantly invaginates the perineum deeply (fig. 6). The end-point is easy to observe and is usually quite precise. If any doubt exists, the disc may be pushed forward, when, in avoiding the resistance of the pubic rami, it rises to lie superficial to the arch once

The assessment of the capacity of the pubic ar made by palpating anterior to the disc at the moment when the rami are tangential to its circumference. It easy, with the fingers invaginating the soft tissues either side of the vulva, to determine whether or not the circumference of the disc extends as far forwards as the pubic symphysis, and, if not, to estimate the amount the gap by means of the centimetre scale provi

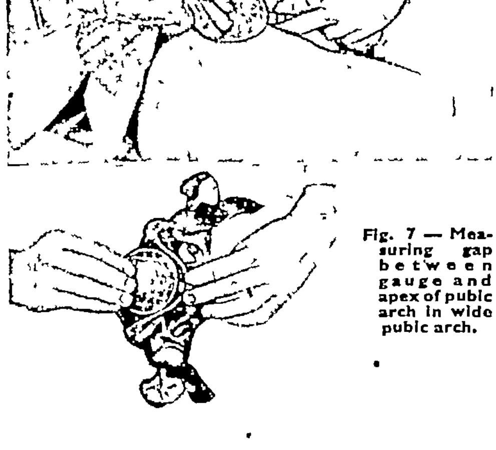

Fig. 7 — Measuring gap between gauge and apex of pubic arch in wide pubic arch.

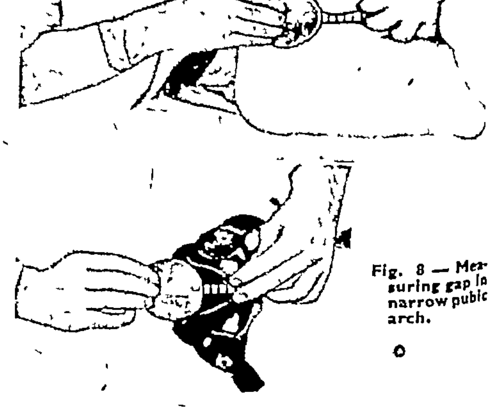

Fig. 8 — Measuring gap in narrow pubic arch.

attention has been paid to the presence or absence sputum. The cultural examination of sputum is erior to either of these methods. Specimens of sputum n 96 cases of minimal tuberculosis detected by mass iography were cultured for tubercle bacilli. Laryngeal ıbs from the same 96 cases were similarly examined. results are given in table III (these cases are ependent of the cases quoted in earlier tables).

Acid-fast bacilli had been found in very few of the itive cases on examination of a stained film of sputum. e results strongly suggest that, if sputum is obtainable l is cultured, there is little point in taking laryngeal abs. A similar conclusion was reached by Clark et al. 45).

DISCUSSION

In comparing two methods of isolating an organism main consideration must be the efficiency of the thods in yielding positive results. If, however, the ference between the methods in this respect is small, her factors may properly be considered.

Advantages of Gastric Lavage over Laryngeal Swab. Gastric lavage gives a slightly higher proportion of sitive results, at least for patients in hospital. Of r 201 patients 45 were positive by laryngeal swab and by gastric lavage. These results approximate those f Hounslow (cited by Clark et al. 1945), who obtained 7 positive by laryngeal swab and 33 by gastric lavage n 99 cases examined by both methods. Minor advantages f gastric lavage are that material is available for direct mear examination and guineapig inoculation. Further, ositive cultures from gastric contents tend to give a eavier growth with more colonies than do positive ultures from laryngeal swabs.

BLE II—RESULTS OF LARYNGEAL SWABS AND GASTRIC LAVAGE IN 101 OUTPATIENTS

No. bacteriologically positive by one or both methods = 19.

Advantages of Laryngeal Swab over Gastric Lavage. —In the ward, and more especially in outpatients, the aryngeal swab is greatly preferred by both patient nd operator. Specimens can be obtained at any time f the day without special preparation; the taking of wo swabs can easily form part of a routine clinical xamination. Patients are willing to allow further wabs to be taken at subsequent examinations, whereas ome would refuse to attend for a second gastric lavage. inally, a specimen can almost invariably be obtained ith a laryngeal swab, whereas gastric lavage is occaionally a failure; even after sucking a benzocain ablet some patients cannot swallow a Ryle's tube. In he laboratory the treatment of the laryngeal swab is impler, shorter, and is the same for all swabs, taking 0 min. for each, whereas the treatment of gastric ontents takes at least 30 min., the time varying ith the volume and consistence of the specimen. aryngeal-swab cultures are less often contaminated (1·5% ontaminated, compared with 3·3% of contaminated astric-lavage cultures), and the colonies are more easily ecognised, because the surface of the medium is clear of ebris.

Time between Collection and Culture.—The exposure f tubercle bacilli to gastric contents for 12–24 hours t room temperature may lead to false negative results Kramer 1946, Sprick and Towey 1946), and laryngeal swabs sent through the post give fewer positive results than those cultured at the time of collection (Clark et al. 1945). Both swabs and lavages should therefore be treated and cultured as soon after collection as possible.

Significance of Positive Finding.—To say how much importance should be attached to a single positive result would require a much larger series with a long follow-up. Attention may, however, be directed to the following facts: (1) Of 71 cases positive by one or both methods only 27 were positive by both. These included a high proportion of those cases in which a positive result might have been anticipated on clinical or radiological grounds. (2) In a separate series of 28 cases positive by laryngeal swabs both swabs were positive in only half the cases. These results suggest the desirability of repeated examination by all methods available, if the maximum of positive results is to be obtained.

SUMMARY

In 100 inpatients and 101 outpatients with radiological evidence of pulmonary tuberculosis but with microscopically negative or no sputum, a search was made for tubercle bacilli by culture of fasting gastric contents and of laryngeal swabs.

Gastric lavage gave slightly superior results for inpatients; there was no difference between the proportions of positive results obtained by the two methods in outpatients.

Patients greatly prefer the laryngeal swab to gastric lavage. Laryngeal swabs can be taken as part of a routine examination without special attendance or preparation.

The laboratory technique for laryngeal swabs is simpler and less time-consuming than that for gastric lavage.

It is not suggested that these methods should take the place of the cultural examination of expectorated sputum, which has been shown in a comparative series to be much superior to the laryngeal swab.

It is a pleasure to acknowledge the help and encouragement we have received from Dr. Robert Cruickshank, director of the Central Public Health Laboratory. Our thanks are also due to the Prophit Committee, Royal College of Physicians, and Dr. W. Snell, medical superintendent, Colindale Hospital.

Since completion of this report Dr. A. G. Hounslow and Mr. G. Usher have reported similiar findings (*Tubercle*, Feb. 1948, p. 25).

OUTLINE OF INVESTIGATION

The investigation was done to provide comparative data on the culture of laryngeal swabs and gastric contents for the isolation of tubercle bacilli; 200 patients (half of them outpatients and half hospital inpatients) were subjected to both laryngeal swabbing and aspiration of stomach contents. Specimens were collected from each patient on the same day or within a few days of each other. Gastric contents were aspirated with a Ryle tube in the morning from the fasting stomach after a period of coughing and swallowing. The material was dispatched to the laboratory as soon after collection as possible and there homogenised and concentrated by a modified acid-peroxide-iron method (*Mon. Bull. Min. Hlth E.P.H.L.S.* 1945, 4, 202). Briefly, this technique consists of adding to the juice an equal amount of a solution of ferrous sulphate in 10% sulphuric acid and 1 vol.% hydrogen peroxide. The acid-peroxide-iron mixture is allowed to act on the gastric juice for 10–20 min., during which time the mucus in the specimen is dissolved. After centrifugation the deposit is washed in sterile Ringer's solution and inoculated on to two Löwenstein-Jensen slopes. As with laryngeal swab cultures, the slopes were examined at weekly intervals and, if negative, discarded after six weeks' incubation. All positive cultures were subjected to the confirmatory tests already mentioned.

Clark et al. (1945) advised the taking of two swabs, since they found a considerable proportion in which only one swab of the pair was positive. Our results confirm the desirability of taking two swabs at each examination. Of 28 cases positive on culture 12 were positive from both swabs, 9 from the first swab only, and 7 from the second swab only.

RESULTS

The results in outpatients and inpatients are considered separately, since the types of case investigated and the conditions of the experiment are not strictly comparable.

Inpatient Series

The patients were all male and were under treatment in a tuberculosis hospital. The types of case varied considerably: 42 of the 100 cases were classed as A cases at the time of the examination, the remainder either B1 or B2. Some were patients recently diagnosed in whom activity was doubtful; others had completed or were having collapse therapy. In all cases the sputum had been negative on one or more occasions to a routine monthly smear examination. The comparative figures for culture of laryngeal swabs and gastric contents are given in table I. It will be seen that gastric lavage yielded 10% more positive results than did laryngeal swabs. The difference between the two is not statistically significant but suggests that, for inpatients, examination of stomach contents was a more sensitive method than examination of laryngeal swabs.

The clinical assessment of this group showed that some cases could be classed as frankly active on radiological and clinical grounds, whereas others were regarded as quiescent. There was an intermediate group in whom the activity was doubtful, either because collapse therapy had only recently been instituted or because of some other factor (such as pleural adhesions) which prevented adequate collapse of the diseased area of lung. The bacteriological findings in these three groups were as follows:

	No. of cases	*No. bacteriologically positive by one or both methods*
Radiologically active ..	.. 25 ..	.. 21
Probably active ..	.. 46 ..	.. 22
Quiescent	.. 29 ..	.. 9

The 4 radiologically active cases that were negative to both tests were positive on sputum culture.

Of this series, 55 patients had received collapse the and 19 of these could be regarded as effectively tre on clinical grounds, but 4 of the 19 gave positive g lavage cultures and 2 positive laryngeal-swab cult The 6 positive cases had disease in both lungs, and 3 of them bilateral collapse had been induced. In 2 o cases the patients were judged unfit for further col therapy, but in one case the positive culture was a the reasons for inducing collapse of the other lung.

Tubercle bacilli were isolated on culture of g contents and/or laryngeal swabs from 22 of 34 pati in whom collapse treatment was regarded as ha been only partially effective at the date of investigat

Outpatient Series

The outpatients were all cases detected by m radiography and so were free of symptoms severe enou to cause them to consult their doctor. Ages ran from 15 to 44 years, and females greatly outnumb males, mainly because more females were being rad graphed. With two exceptions the lesions were radi logically minimal as defined by the National Tubercul Association (1940). The results are given in table II

The results for the two methods do not differ signi cantly from each other. The outpatients showed a high proportion of positive cultures from laryngeal swa than from fasting gastric contents. The difference i small and most likely due to chance variation. Since the work was done in outpatients there was inevitably an interval for travelling between rising and the collection of the specimen. This was usually at least half an hour and often more. Gastric movements in this period would possibly cause some of the contents to pass int the duodenum; relatively small volumes of fastin contents were obtained.

The series is far too small for conclusions to be dra about the value of such tests in the prognosis of m lesions detected by mass radiography. However t position some nine months after the work was comp was as follows:

> Of the 82 negative by both methods when first seen 4 w assessed active on other grounds, 6 showed definite sign activity within nine months, and 8 were possibly a within nine months—i.e., a maximum of 18 out of 82 sho signs of activity.
>
> Of the 19 positive by one or both methods 2 had cav (the cases mentioned above as being other than mini and 12 showed definite evidence of activity either at the examination or within nine months—i.e., at least 14 out gave radiological or clinical confirmatory evidence of act Of the remaining 5 patients, 4 women were advised to treatment because of the radiographic appearance single positive bacteriological finding, and 1 man, aged has remained at work clinically well, radiologically st and without tubercle bacilli again being isolated.

COMPARISON OF SPUTUM CULTURE WITH LARYNGEAL-SW CULTURE

The main object of this paper is to compare the cultu examination of fasting gastric contents with that laryngeal swabs for isolating tubercle bacilli. Accord

In November, 1946, she had several septic spots on her ce and the eye condition was very pronounced. In March, 947, she had a slight antral infection accompanied by a are-up in the eyes. In September she noted that she had ores on her fingers, and that when they were bad the eyes ere bad also. In October she had a stye on the right wer lid and a septic spot on her face, both yielding a rofuse growth of hæmolytic *Staph. aureus*, and at the ame time there was an acute exacerbation of the eye ondition.

In view of this cumulative evidence it was considered robable that the conditon was due to the staphylococcus, nd she was admitted to hospital and given penicillin 25,000 nits three-hourly intramuscularly to a total of 1,000,000 nits. At the end of the course the inflammation had ıbsided, and there has been no recurrence in the subsequent ree months except for a slight flare-up when she had a bad old in December.

Though the eye condition reacted to the larger doses f tuberculin, there can be little doubt, in view of the evere exacerbations when she had local staphylococcal ıfections, and the complete and lasting subsidence of he condition after treatment with penicillin, that the ause was an allergic reaction to the staphylococcus.

Medical Societies

EDINBURGH OBSTETRICAL SOCIETY

Surgery in Cervical Carcinoma

AT a meeting on May 19, with Dr. W. F. T. HAULTAIN, he president, in the chair, the rôle of surgery in the reatment of carcinoma of the cervix was discussed by Ir. CHARLES READ. Opinion, he said, was divided on he relative merits of radiation and radical surgery in tage-1 and stage-2 cases. There was little debate in espect of stage-3 and stage-4 cases, which were generally ınsuitable for surgery. While in many clinics the Vertheim operation had been abandoned when radiotherapy had been generally established, at the Chelsea Hospital for Women this operation had been performed ontinuously since Mr. Bonney introduced it in 1907, lthough lately cases had been selected rather carefully. Even the surgical enthusiast must admit that the results of radiotherapy compared favourably with those of urgery; but it might well be asked whether any of the atalities after radiotherapy could be avoided by judicious urgical procedures.

Mr. Read suggested that there were seven indications for a surgical attack upon cervical carcinoma: 1) radio-resistance proved clinically or cytologically; 2) columnar-celled carcinoma of the cervix; (3) vaginal-vault stenosis; (4) large fibroids or ovarian cysts complicaing the growth; (5) salpingitis with cervical cancer; 6) refusal of radiation by the patient; and (7) pregnancy complicating cervical carcinoma. Previous irradiation, ıe said, increased the technical difficulties of the Wertheim operation: but this operation was justifiable in proved adioresistant cases, for at the Chelsea Hospital the ive-year survival-rate was 44·4% in 34 stage-1 and 20 stage-2 growths. He had found that the incidence of gland involvement was roughly as follows: stage 1, 20–25%; stage 2, 30–35%; stage 3, 40–50%; and stage 4, over 60%. It appeared that treatment by adium alone, using only vaginal applicators, could ıever give adequate radiation to the lymphatic field. Thus there seemed to be a place for iliac lymphadenectomy in stage-3 cases which had been cured ocally by radium; and such a procedure could well oe extended to include stage-2 cases and selected cases n stage 1.

Mr. Read discussed the technique of the Wertheim operation. He referred especially to lymphadenectomy early in the operation, leaving the iliac and obturator lymph-node chain attached to the uterus throughout; to the need for removal of at least the upper half of the vagina; and to the use of plasma or blood-transfusion. He reported an incidence of postoperative urinary fistulæ of 3·1%.

Prof. ROBERT MCWHIRTER said that his own opinions were governed not only by technical considerations but also by certain general principles. Of these he placed first the need to consider each case of cancer individually, and to treat the patient and not the tumour. The prime object should be to make her more comfortable, and any treatment which cured the cancer without achieving this end was a failure.

The maximum distance from the cervical canal at which radium might be expected to be effective was 3 cm.; growths which extended beyond that distance were insusceptible to radium. The tumour lethal dose varied, and some tumours might justifiably be described as radioresistant; but the most important limiting factor was the restricted striking distance of radium. For improved assessment of radiosensitivity a new histological approach was needed. Possibly observation of the effects of irradiation through successive biopsies might prove a valuable field of investigation. It was difficult to envisage any great increase in radium range in the near future, apart possibly from improved applicators with more efficient screening of the bladder and rectum; dosage was restricted chiefly by the need to avoid damage to these organs.

When radium treatment was first supplemented with X rays, the whole pelvis was irradiated; and not uncommonly necrosis resulted in tissues which had already received a high dosage from radium. It became obvious that if X-ray treatment was to be really beneficial, it must be closely aligned to the radium treatment. Cases with cells just outside the effective range of radium were far more likely to benefit from X rays than cases with cells far out in the pelvis, for in this advanced condition there were often also distant metastases. In an attempt to align the two methods of treatment, the X-ray fields were planned from radiographs showing the position of the radium in the uterus: but with vaginal packing the uterus might be greatly displaced to one or other side of the pelvis and it might be considerably displaced upwards. These difficulties could be overcome to some extent by special radium applicators, such as those devised by Richards, of Toronto. X-ray therapy alone would remain unsuitable until much more powerful apparatus was introduced.

Professor McWhirter believed that surgery was the most effective method of treating early and localised cancer. Because extensive lymphadenectomy must always remain a piecemeal dissection, he thought it unlikely that this practice would greatly improve the eventual prognosis. He did not believe that an inoperable case could ever be rendered operable by preliminary irradiation, although he believed improvement might be obtained by means of postoperative irradiation with very high voltage X-ray apparatus; and preoperative irradiation might benefit operable cases. In a review made some time ago, the five-year survival-rate in Edinburgh was 29% of all cases referred. In the most recently analysed cases, the five-year survival-rate was 34%. He believed that these figures might be improved by the use of surgery where the disease was early and where the tumour was shown to be radioresistant.

"... Has there occurred, or has there not, so radical a change in world food prospects as to call for a complete reversal of British economic policy? ... The demand that counts is effective demand. The effective demand of the would-be eaters consists overwhelmingly in their capacity to supply things for which the food producers are willing to exchange food ... F.A.O. or no F.A.O., Atlantic Charter or no Atlantic Charter, it is certain that the citizens of the United States, Canada, Argentina, and the other food-producing countries are not going to tax themselves year in, year out, to buy food from their farmers and supply it to Asia gratis. ... In the last resort the British food problem is ... a question not of the availability of food in the world but of Britain's ability to pay for it. ... There is a strong probability that more abundant and cheaper supplies of food will be available for Britain to buy some time before very long; and there is some possibility that food will again become as cheap as it was. But no one can be sure of these things ... and it would be wrong to base an irrevocable policy on one particular reading of them.—*Economist*, July 17, p. 94.

CYSTICERCOSIS CEREBRI MISTAKEN FOR CEREBRAL SYPHILIS

REPORT OF A CASE

A. A. Williams
M.B. Lond. M.R.C.P.E.
DEPUTY MEDICAL SUPERINTENDENT, MIDDLESBROUGH GENERAL HOSPITAL

The following case is reported because of the difficulty in diagnosis.

A man, aged 29, had been a regular soldier and had served seven years in India. There was no history of venereal disease. In 1943 he was discharged from the Army because of epileptic fits attributed to cerebral syphilis. Presumably the blood Wassermann reaction (W.R.) was then positive, but there is no record of this, nor of any antisyphilitic treatment. On discharge from the Army the patient reported to the Middlesbrough General Hospital, as he was having repeated attacks of epilepsy.

He had a slurring speech and there was some mental dullness. Both optic discs showed early optic atrophy, but no other physical signs were found. The blood W.R. was negative. In the cerebrospinal fluid (C.S.F.) the W.R. was negative and the Lange colloidal-gold test gave a paretic curve. *Ventriculography by the neurosurgical unit of another* hospital yielded no evidence of cerebral neoplasm.

The patient had three courses of bismuth, each consisting of twelve injections of 0·2 g., without benefit. During this period he was admitted to hospital on several occasions in status epilepticus. A course of penicillin and malaria therapy was begun in August, 1945, but the penicillin course was not completed as the patient refused injections. No improvement followed treatment, and fits were not controlled with phenobarbitone and 'Epanutin.'

On June 18, 1946, the patient was admitted semi-conscious: stertorous breathing; pulse of good volume and tension; nothing abnormal found in heart and lungs; pupils constricted and equal; biceps, triceps, and supinator jerks, knee-jerks, and ankle-jerks present and equal on both sides; abdominal reflexes doubtful; no definite plantar response obtained. By June 21 he had completely recovered consciousness but was rowdy and difficult. Cranial nerves normal; reflexes as before, except that plantar response was definitely flexor on both sides; no sensory loss; and bilateral atrophy of optic discs, worse than on previous examination.

On July 1 the patient had an epileptiform attack, after which he continued to have frequent attacks, localised to the angle of the mouth (right side), about every 3 minutes. There was no loss of consciousness. During this period weakness of the muscles supplied by the right facial and the right spinal accessory nerves developed. These fits were completely uncontrolled with phenobarbitone and epanutin.

Examination of C.S.F. on July 21: lymphocytes 10 per c.mm., protein 80 mg. per 100 c.cm., gold curve 1222221000, W.R. negative, and Kahn test negative. Blood: W.R. and Kahn test negative; white cells 10,600 per c.mm. (polymorphs 79%, lymphocytes 13%, monocytes 1%, eosinophils 7%). The possibility of cysticercosis cerebri was considered, but no nodules were discovered on palpation in any part of the body, and radiography of skull and both thighs did not reveal any calcified ova. Skin complement-fixation test not done.

The patient was discharged on July 30 with a diagnosis of epilepsy of unknown cause. He was not seen again until readmission on *Oct. 13* in status epilepticus. *Generalised* epileptiform convulsions were occurring every 5 minutes and were uncontrollable. He did not recover consciousness, and died on the 16th.

Necropsy.—Dr. W. Goldie reported as follows: "The surface of the brain is studded with considerable numbers of small cysts varying in size from about 5 mm. up to 20 mm. in diameter. The cysts show differing stages of development; most of them are quite translucent and contain clear fluid. The cysts have also invaded the substance of the brain. A typical scolex was demonstrated histologically in one of the cysts. The appearance and size of the cysts are consistent with a diagnosis of cysticercosis, and their situation in the brain would certainly account for the previous history of epilepsy." A careful search of the muscles of the thighs, gluteal region, shoulders, upper arms, and spinal muscles did not reveal any cysticercus ova. No gross changes in any other organs.

MacArthur (1934) pointed out the importance of considering cysticercosis as a cause of epilepsy in persons who have lived in the tropics. The incidence of cases may become greater in this country with the return of troops who have been stationed in the East during the war. Cerebral *cysticercosis, however, does not always* cause epilepsy (Dixon and Smithers 1934, Marsh 1934, Dixon and Hargreaves 1944, Edwards 1946). MacArthur (1934) mentioned that it has been diagnosed as hysteria, cerebral tumour, acute encephalitis, melancholia, delusional insanity, and dementia præcox. Stokes et al. (1945) remarked that, as in the present case, it may have to be differentiated from cerebral syphilis.

The diagnosis is made difficult by the facts that unless the cysts are calcified they cannot be demonstrated by radiography, and, according to MacArthur (1934), both the eosinophilia and the complement-fixation test are unreliable; even during the acute invasion stage an eosinophilia may not be present.

No records of the results of the original blood and C.S.F. Wassermann reactions are available in this case; but, in view of the diagnosis of cerebral syphilis, it is presumed that on the patient's discharge from the Service the blood W.R. must have been positive. If so, the result may have been a biologically false positive, as the Wassermann and Kahn tests after discharge were consistently negative. This emphasises the importance of frequent repetition of serological tests in doubtful cases of syphilis.

A further difficulty in diagnosis in this case was the presence of optic atrophy, which is unusual in cysticercosis *but has been reported by MacArthur (1934)* and Edwards (1946).

My thanks are due to Dr. T. Lloyd Hughes, medical superintendent of the hospital, for permission to publish this case, and to Dr. W. Goldie, pathologist, Public Health Laboratory, Northallerton, for his report and his help in preparing the paper.

PHLYCTENULAR KERATO-CONJUNCTIVITIS TREATED WITH PENICILLIN

R. W. Stephenson
M.R.C.S., D.O.M.S.
OPHTHALMIC SURGEON, CHELTENHAM GENERAL AND EYE HOSPITAL

Phlyctenular kerato-conjunctivitis is agreed to be an allergic condition, the commonest exciting cause being *a tuberculous focus. In the following case Staph. aureus* appears to have been the exciting agent.

In 1930 a girl, aged 5 years, had mild chronic nasal diphtheria and was a carrier for some time, during which she developed phlyctenular kerato-conjunctivitis. She had several relapses of the eye condition until 1942, after which she remained clear until August, 1946, when she had a severe phlyctenular condition in both eyes. From then until October, 1947, the condition was active, varying in severity. There was no sign of active tuberculosis, but the tuberculin test was strongly positive. Treatment with Old Tuberculin was tried, starting with 0·1 ml. of 1 in 1,000,000 solution; 0·6 ml. caused a slight reaction in the eyes, and 0·7 ml. caused a considerable flare-up.

THE LANCET

LONDON: SATURDAY, JULY 24, 1948

Atomic Defence

THE Armed Forces in the United States naturally e their doctors to have a working knowledge of e principles of atomic radiation, the protection of ople handling radioactive materials, the treatment those exposed to radiation, and the possible methods minimising the effects of this exposure The sentials were lately summarised in a symposium[1]; ut when this has been assimilated there remains the uestion, present in everyone's mind since Hiroshima: hat can really be done if an atomic explosion does ccur, by accident or design? King[2] essays an nswer in his article, but it is scarcely an encouraging ne. He admits that there is as yet no satisfactory rotection against the streams of particles and the ays that are the result of an atomic explosion. After uch an explosion there is an innermost area containing lethal concentration of radiation in which it is useless aste of man-power to attempt rescue work. Outside his lethal area, however, much can be done by proper rganisation, and in this organisation doctors have a rominent part to play.

The American commission of investigation found hat 260 out of Hiroshima's 300 doctors were unable o assist in treating the wounded: yet King estimates hat if there was an atomic attack on an American ity at least a thousand doctors would be needed or weeks to treat affected and wounded people, to supervise the decontamination of people and areas, and to advise the military and civilian officials. In King's view this calls for decentralisation. Hospitals and medical centres must be well away from centres of industry and population. Blood-banks form an important part of atomic defence, since blood-transfusion is the only known treatment for radiation sickness; therefore blood-banks must be established —again at the periphery of areas—with enough equipment to give at least a pint of blood to each person in the area served by the centre. Trained teams will be needed to operate these banks and "adequate reserve technicians" should be available. Food and drugs in the affected area will inevitably become contaminated: so stores of non-perishable foods and drugs must be established outside likely areas, preferably in underground shelters. In the Bikini experiment massive doses of penicillin were used, with good results, to prevent infection in the exposed animals; so King would have stores of "huge quantities of antibiotics," known and yet to be discovered, with equipment for their administration, all to be replaced as necessary. Another point to be considered is that water-supplies may be contaminated in reservoirs by radioactive material in rain or carried by the wind; so reserve water-supplies from deep wells or large distillation plants are proposed. Decontamination centres were a familiar part of civil defence in this country: and they would be all the more necessary with atomic radiation, since anyone from a "dirty" area would need to shed all clothing and all personal belongings, scrub down in running "clean" water, and put on fresh clothes The disposal of the "dirty" clothes and water presents peculiar problems, and King suggests that the site of disposal should be in the contaminated area itself. Something can be done to protect the rescue-worker with special clothing and special masks. Masks should be provided for everyone and King would have the population educated in their use beforehand. Real protection could only be obtained in underground shelters with at least 5 feet of concrete for the roof, and since people would have to stay in the shelters until all dust, water, and spray had settled they would have to be properly equipped. Finally there is the question of evacuation of casualties and of population when a town's services have become seriously disorganised. Experience suggests that communications in a large area would be completely disrupted, and in fact it would not be worth evacuating people from the central area since they would have been exposed to lethal radiation and would all die sooner or later even if they survived the blast. In most cities as now built disruption at the centre involves lengthy detours: King regretfully admits that it is not practicable to "revamp the nation's communication system," but he would like to see new buildings planned on the radiating-spoke system with peripheral circular connecting roads, as these would be ideal for atomic defence.

This then is the outline of an atomic-disaster plan, and King naively hopes that a thorough understanding of it will help in combating the "atomic neurosis" We have our doubts. The plan is hardly inadequate, yet it seems to involve the entire replanning and redistribution of hospital services, with all the waste of time and energy that travelling to and from a peripheral centre would involve. Great stores of equipment and material must be formed and sterilised—and all of materials of which we cannot get enough for our peace-time needs. The very water-supplies and communications system must be altered. Houses must be built to the windward of industrial plants or military targets. Thousands of blood-donors must be listed. (King seems to think it will be easy to locate them when the time comes, but experience in this country under attack showed how much organisation and effort was needed even for this one aspect of defence.) Then the population must be ready to abandon their friends in the central area, and must not go searching for relatives or worrying about their personal problems: if this were allowed, says King, there would be no-one left to conduct the rescue programme! Surely such a scheme places impossible burdens on a population in times of peace, most of whom are having a hard struggle to maintain a decent standard of life for ordinary activities. It is true that even this country might survive the damage caused by a small number of atomic bombs, and it is reasonable to consider what we should do if we found ourselves partially but not

Reviews of Books

Radon: its Technique and Use

W. A. JENNINGS, B.SC., A.INST.P., physicist to the Royal Northern Hospital and Prince of Wales's General Hospital joint radiotherapy centre, London; S. RUSS, C.B.E., D.SC., F.INST.P., formerly physicist to Middlesex Hospital. London: John Murray for the Middlesex Hospital Press. 1948. Pp. 222. 18*s*.

RADON for medical purposes in this country has mostly been prepared at the Medical Research Council's radon centre, and this book is based on experience gained there. It has three main sections: the first deals with the physical properties of radon and briefly surveys its applications; the second describes in some detail the preparation, loading, and measuring of radon sources, and also discusses the (seemingly inevitable) variation in the strength of sources; while the third is devoted to the applications of radon in radiotherapy, and has a chapter by Mr. T. Anthony Green on his techniques for the more accurate use of radon "seeds." The second section is probably the most valuable, containing much information which will be very useful to those who work with radon purification plants. The other sections would be improved by removal of some repetitions and possibly by more critical selection of treatment-planning methods already fully discussed in a number of recent books. The space saved could be used to include a comparison of the efficiency of the apparatus described and of other designs.

It is unfortunate that radon "seeds," made by pumping the gas directly into gold capillary tubing, are dismissed in a footnote as not admitting of the refinements developed by the authors. Actually, G. E. Eddy in Australia has developed the gold capillary method (which has many advantages over glass capillary) to a higher state of flexibility and accuracy than is found, probably, anywhere else in the world.

Die Bedeutung der Seelenkunde von Klages für Biologie und Medizin

Dr. med. E. FRAUCHIGER, professor of comparative neurology, University of Berne. Berne: Huber. 1947. Pp. 99.

ALTHOUGH Klages has been writing for nearly forty years, his philosophy is very little known in English-speaking countries, and his characterology is not applied in medicine or psychology, except by the few students of handwriting who have profited from studying his many contributions to this subject. Abstruse and pessimistic though his views are, they contain much that is relevant to the problems of psychiatry. Professor Frauchiger, an enthusiastic disciple of Klages and a teacher of comparative neurology and psychiatry in the University of Berne, shows in this book how the philosopher's conceptions illuminate personality, and especially the psychopathic personality. Klages will not accept the common assumption that several essential kinds of psychopathic personality and neurosis can be classified: he holds that there is one psychopathy, the outcome of conflict between will and instinct, which results in a reduced sense of reality and by its combination with many sorts of character gives rise to the familiar neurotic variants. Dr. Frauchiger touches on the relation of Klages's views to those of Monakow, his criticism of the typology of Jung, and his reasons for disputing the psychoanalytic theory. From this work no-one could grasp the full philosophy of Klages, but it will direct philosophically minded physicians to a writer who has struggled manfully to anatomise human character.

Anatomy of the Eye and Orbit

(3rd ed.) EUGENE WOLFF, M.B. Lond., F.R.C.S., ophthalmic surgeon, Royal Northern Hospital, London. London: H. K. Lewis. 1948. Pp. 440. 45*s*.

MR. WOLFF's continued interest in the microscopic anatomy of the eye has led to a further enlargement of this book, which now contains 130 more pages than the last edition. The standard of production is as good as before, and the whole has been made more attractive by the addition of several coloured plates—photomicrographs and anatomical paintings. The general arrangement remains the same, but new work has been included on a variety of subjects. Some is work done by Mr. Wolff himself—including studies of the distribution of the lacrimal fluid, the precorneal film, and the mucocutaneous junction of the lid margins. He also describes Fincham's investigations on the mechanism of accommodation, and those of Michaelson and Campbell on the retinal capillaries, and quotes extracts from Le Gros Clark's Doyne lecture on the central connexions of the visual apparatus.

This is a splendid book, of equal use to student and surgeon, and containing all that is proved of the macro- and micro-scopical anatomy of the eye. As pathologist and surgeon to the Moorfields, Westminster, and Central Eye Hospitals, the author has had great experience of his subject, and he more than upholds the prestige created by his earlier books.

Human Physiology (3rd ed. London: J. & A. Churchill. 1948. Pp. 592. 25*s*.).—In this edition of their convenient textbook, Prof. F. R. Winton and Mr. L. E. Bayliss, PH.D., have arranged that several sections should be written by colleagues expert in various fields—a policy begun in the second edition and now extended. The book as a whole has been revised, and trouble has been taken to treat the whole subject in a balanced way. The illustrations, always good, have been increased.

ABC of First-aid Treatment (British Red Cross Society. Foreword by Air Marshal Sir Harold Whittingham, F.R.C.P. London: B.R.C.S. 1948. Pp. 28. 1*s*.).—This is a great improvement on the older type of first-aid manual. The different emergencies are listed alphabetically opposite whole pages of the corresponding illustrations, so that the concise and essential instructions are automatically associated with the visual image. The booklet will be invaluable at every first-aid point.

Archives of Neurology and Psychiatry (Vol. 25, 1941. London County Council, 1947. Obtainable from Staples Press Ltd., 14, Great Smith Street, Victoria Street, London, S.W.1. 30*s*. 0*d*.).—This collection of reprints, edited by Prof. A. J. Lewis and Prof. S. Nevin, was ready in 1941 but its distribution was interrupted by the war. The papers come from the staffs of the L.C.C. Central Pathological Laboratory, the Maudsley Hospital, and the London County Hospitals for Nervous and Mental Diseases, and cover a wide range of subjects, many with current, and some with permanent, value. The volume also carries a list of war-time publications by the staffs of these hospitals and of the Central Pathological Laboratory, which serves to indicate the work they undertook during the years when the *Archives* were not appearing.

Some British Pioneers of Social Medicine (London: Oxford University Press. 1948. Pp. 118. 12*s*. 6*d*.).—Very suitably, the Heath Clark lectures given by Prof. Major Greenwood, F.R.S., in 1946, have appeared in book form at the centenary of Sir John Simon's appointment as the first medical officer of health to the City of London. They are less a history of the British sanitary movement than a tribute to those who took the largest part in it. Half the book is devoted to Chadwick, Farr, and Simon, of whom Professor Greenwood says: "few who pass their memorial plaques on the façade of the London School of Hygiene could say what any of these men did and of the few more would remember Chadwick than Farr or Simon." His own preference is for Farr, with whom he has the greatest sympathy; but he admits that, of the three, Chadwick had much the greatest influence on the sanitary conscience of the people. Chadwick had received no scientific training; indeed, he had no science of his own, and what he borrowed was not always culled from the best sources. He was no orator, and his writings are forgotten; but he was a man of action. Having little care for himself, he ordered people about, and made many enemies, who eventually prevailed and drove him from office. Simon was intellectually far ahead of Chadwick, but he was more careful of himself, though he too fell from power for reasons which are not quite clear. Both lived to an advanced age in retirement.

The book is written with Professor Greenwood's usual skill and will be read with special pleasure by those who know him and share his interest in the development of biometry.

ule, beginning at the junction of the connecting ule and the terminal part of the distal convo- ed tubule. At 17 hours the intraluminal hæmoglobin l increased and in cleared thick sections a few hrons were thus outlined in their entirety; at hours most of the nephrons were so delineated and glomerular spaces too contained hæmoglobin. ter (113 hours) tubule walls ruptured and hæmo- bin escaped to the interstitial spaces, except ally where it "plugged" the tortuous tubule; r still (161 and 185 hours) the intraluminal hæmo- bin had further diminished and some reaction had urred around the escaped material. At 329 hours ost all the proximal convoluted and other seg- nts of the tubule were lined by normal epithelium; ew atrophic tubules contained dense masses of mosiderin Some tubule dysfunction was a conse- ence of the high level of hæmoglobinæmia in these periments—about 1 g. per 100 ml., corresponding that seen in man after hæmolysis of about 400 ml. whole blood About 70 hours after the initial d 20 hours after the final) injection the urinary tput dropped to 15% of the previous value; and s oliguria seemed to be associated with slowing of flow through the lumen of the nephron, a conse- ence of the increased viscosity of the protein-rich id, as well as with the degree of athrocytosis

In rabbits, hæmoglobin "nephrosis" can be oduced consistently when the animals are deprived water and then given repeated injections of hæmo- obin Yorke and Nauss[3] originally pointed out at the preliminary feeding of rabbits on dry oats creased the severity of the hæmoglobin nephrosis sulting from subsequent intravenous injections of emoglobin, and Flink[4] showed that the intravenous jection of hæmoglobin into dogs not deprived of ater was followed by hæmodilution and he suggested at the hæmodilution aided the excretion of the emoglobin in the urine. Lalich[5] has confirmed rabbits) that when available fluid is first depleted depriving the animal of water, hæmoglobin tering the renal tubules results in the formation of gment casts. He also reported dilatation of some structed tubules and focal necrosis of other tubules rabbits which developed uræmia. Bywaters and tead,[6] by combining dehydration with acid diets in bbits, found that compression of the leg muscles d the injection of human myohæmoglobin produced yohæmoglobinuric nephrosis In crush syndrome yohæmoglobinuric nephrosis[7]) and mismatched ansfusion (hæmoglobinuric nephrosis) the main nal lesion is in the ascending limb of Henle's loop d in the distal convoluted tubule, which show varying grees of necrosis, desquamation, and later epithelial generation; and pigment casts are not uncom- only found in the collecting and distal convoluted ibules From studies in these two conditions and om experimental work Bywaters[7] concluded that pigment nephrosis there is a direct physiological esorption) block in the renal tubular epithelium, and e recent studies in renal athrocytosis support his view.

Nevertheless, the occasional paucity of pigment and pigment casts in crush-syndrome kidney[8] and in blackwater fever[9] suggested that some factor other than simple obstruction operates to cause failure of tubule function in these and allied conditions. Maegraith and Findlay[9] suggested that a redistribution of the intrarenal blood-flow, in which the cortex was mainly bypassed, was partly responsible for degenerative changes in the highly specialised tubule cells; earlier Rigdon[10] had emphasised the rôle of anoxia resulting from the anæmia of malarial infection, and "renal anoxia" as a functional concept was also advanced by Tomb[11] Following release of 4–5 hours of complete limb ischæmia in chloralosed cats Keele and Slome[12] recorded a sharp fall in renal blood-flow (to about 30% of its initial value)—more than could be accounted for by the fall in blood-pressure. Later Trueta and his co-workers[13] described their tourniquet experiments, designed to simulate crush syndrome in man, and reported arterial vasoconstriction, apparently extending proximally from iliac to renal arteries, which greatly reduced the renal cortical blood-flow, and, by diversion, augmented and accelerated the medullary blood-flow. This mechanism has been said to operate in human crush syndrome; but these tourniquet experiments were of the "acute" variety and none of the animals lived long enough to develop tubular lesions and the associated oliguria, anuria, and uræmia Bywaters[7] complains that reflex vasospasm is too freely used by various writers to account for crush syndrome anuria Too little regard is now paid to the long-recognised autonomous capacity of the kidney to maintain its blood-flow in face of variations in the general circulation and of changes in bodily posture.[14] Severe tubule dysfunction and oliguria with attendant electrolyte upset and uræmia occur in some cases of abortion, with moderate to severe blood-loss and vomiting,[15] in which, as after hæmatemesis and melæna,[16] there is a great reduction in glomerular filtration and in renal blood-flow.

Similar disorders of tubule function occur in a variety of other conditions, including incompatible blood-transfusion and blackwater fever, as well as in crush syndrome In reviewing the common factors causing renal failure in these conditions Foy et al.[17] emphasise dehydration, with diminution of blood-volume, renal blood-flow, and glomerular filtration, rather than tubule blockage as the cause of the anuria. Dehydration is also a common factor in other conditions in which tubular lesions and acute renal failure are described—excessive vomiting in pyloric stenosis, cholera, Weil's disease, yellow fever, and concealed accidental hæmorrhage General depression of renal blood-flow (with autonomous renal adjustment) will affect most those distal tubules

fatally injured. But that is a very different matter from the proposal that we (and presumably the people of all other countries) should henceforward make defence (active or passive) the chief end and aim of our existence.

Tuberculosis in Scotland

THE effect of the late war on the death-rate from tuberculosis is well known. An increase was one of the expected evils, and it came with explosive suddenness. Nevertheless for some unexplained reason the peak reached in 1941 was followed by a fall, which in England was continuous, and by the end of 1945 the English death-rate was the lowest on record. In Scotland the fall was slower, but it too was progressive, and the tuberculosis deaths during 1945 (3803) were 9% fewer than those of 1941 (4175) though they were still more than 10% above those of 1938 (3431). The fact that the disease is one which usually lasts for years makes it unwise, however, to base any forecast solely on recent mortality figures; and despite the fall in the number of deaths there have been other and perturbing trends.

The rise in the incidence of tuberculous meningitis which was seen both in England and Scotland during the early years of the war could only be interpreted as evidence that infection was being diffused among a young population which had hitherto partly escaped. It was greatest in Scotland, and in its peak year—again 1941—it reached a figure 48% above that of 1938. Moreover, while deaths fell, notifications in Scotland rose by 1943 to an annual total of 10,088, the highest since 1929, and the respiratory portion of the total was the highest since 1926. Notifications fell during 1944, remained stationary in 1945, and again rose during 1946 and 1947, when they totalled 9973. Admittedly there are fallacies in notifications, but it is hard to account for the great increase. Those who watched the rising figures awaited with misgiving the harvest they portended, and the first evidence of that came in 1946, when the death-rate, after its steady slow fall, rose suddenly to that of 1942. Last year it was almost back to the peak figure of 1941; and Mr. WALTER ELLIOT, speaking on the Scottish health estimates in the Scottish Grand Committee of the House of Commons on July 1, did well to draw attention to a situation which is, as he says, disquieting.

It is difficult to see the facts in perspective. Conditions of life probably differ little in England and Scotland, taken as a whole; but in both countries they differ greatly from district to district. There is little doubt that tuberculous infection has become more widespread in the industrial areas of Scotland: and if we remember that some 40% of the Scottish population is congregated in the industrial belt of the West, where conditions of life and housing leave much to be desired, we may find a partial explanation of the big increase of notifications and the rising death-rate. This increase will certainly dispel any complacency based on the falling mortality figures of the past six years, and it should also dispel any hopes of conditions righting themselves. In Scotland the number of infectious patients in the community has increased at a time when it grows harder and harder to give institutional treatment to those who ought to have it. Treatment in the home is therefore more and more required; but so long as houses are overcrowded it will remain impossible to secure the isolation needed if such treatment is to be safe. In considering the present situation we cannot ignore, either, the possibility that the disease may be favoured by some of the present restrictions of diet. Tuberculosis has always been a problem of the adolescent and it is taking a disproportionately heavier toll of the young. Among Scottish women in 1947 the death-rate from tuberculosis of the lungs was 63 per 100,000; but in the age-groups 15–25 and 25–35, the ages of adolescence and full fertility, the rates were 142 and 147. Quite possibly the food nowadays consumed by young adults does not fully meet their needs for protein or perhaps for fat; and we are still faced with the vicious circle of increased infection, overcrowding, and poor nutrition. At the back of it all are the economic effects of war, which dominate the national life and the life of the individual

Renal Tubule Dysfunction

MOST students of pathology know that at necropsy the kidney gives a positive prussian-blue reaction in pernicious anæmia, acholuric jaundice, and other hæmolytic anæmias; that this is due to hæmosiderin present in the tubule cells; and that hæmosiderin is the iron-containing moiety remaining in the cells after katabolism of hæmoglobin removed from the glomerular filtrate at times of hæmoglobinæmia. Most too are familiar with the fatty appearances of the kidney and fatty casts in the urine in various forms of nephritis and "nephrosis," and they will also recall the hyaline droplets formed in the renal epithelium which are likewise associated with increased glomerular permeability the result of glomerular damage. These conditions are manifestations of renal athrocytosis, described by PAUL GÉRARD[1] as the characteristic property of the vertebrate nephron—the resorption of electronegative colloids through the apical surfaces of its cells, which become increasingly permeable from the proximal to the distal end of the striated border segment of the nephron.

In health the human glomerular capillary membrane is impermeable to molecules of the size of the plasma proteins, and albuminuria is usually taken as evidence of glomerular damage, save perhaps occasionally where it follows exertion. The hæmoglobin molecule (molecular weight 68,000) is about the largest to pass through the normal glomerular filter, and RATHER[2] has used hæmoglobin as a "marker" substance in the study of renal athrocytosis. He gave rats intraperitoneal injections of purified human hæmoglobin 1 g. twice daily for five injections, and found that 2 hours after the first injection (when the hæmoglobin had been absorbed into the blood-stream and reached the glomerulus) there were particles of stainable hæmoglobin in the epithelial cells of the proximal convoluted tubules, and at 17 hours the cells were packed; demonstrable hæmosiderin was maximal at 65 hours. While the tubule cells were becoming sated with hæmoglobin, a more concentrated form of hæmoglobin appeared and accumulated within the rk—than the more placid long-distance man. The lue of glucose and alcohol is chiefly psychological. cohol in moderate amounts with meals may help to rd off staleness. Though the first to suggest that ucose should be taken immediately before races, he w believes that its effect is due principally to the easant sweet taste.

[1] Gérard, P. *J. Anat*, 1936, 70, 354.
[2] Rather, L. T. *J. exp. Med.* 1948, 87, 163.

Physiological research in the twelve years since the st Games has strengthened the hypothesis that in e production of energy carbohydrate, fat, and protein ally follow a common path; it is now virtually certain at these three main energy foods are partly or wholly terconvertible. Thus it seems that the athlete in aining will do well to follow his own likes and dis-kes; in satisfying his appetite he will get the carbo-ydrate and proteins he requires. He need take no tamin pills or glucose tablets, and he should drink eely—not necessarily avoiding alcohol with meals, ovided that the amount is moderate.

COST OF CONVALESCENCE

As things stand at the moment, some patients have pay for convalescent treatment while others get it ee. There are three categories of convalescent homes:) a relatively small number transferred to the National ealth Service; (2) a few that successfully appealed ainst such transfer and were "disclaimed"; and) a relatively large number remaining outside the service, ich the Ministry of Health classes as "holiday homes." ough the regional boards are required to pay for tients in transferred and disclaimed homes, they ve no power to pay for patients in holiday homes; d the methods of supporting hospital patients in this st and largest group still seem to be uncertain. The cal authorities, it is true, have powers under section 28 the Act to pay for aftercare, and this is sometimes ken to include convalescence: but the idea is new, d though the authorities generally agree to it, it ay be some time before any payments are actually ade. Meanwhile, King Edward's Hospital Fund Emer-ncy Bed Service, which has agreed to provide, on quest, information about vacancies in convalescent mes, finds that *a curious situation is developing.* All es are fully booked, but the transferred and dis-med homes have long waiting-lists, while waiting-s for the holiday homes are much shorter. It is rly only a matter of time before patients in holiday nes ask: "Why am I paying, here, when Mrs. So-and-was sent to a convalescent home for nothing?"

he regional boards are trying to arrange that the al authorities should meet the cost for patients sent holiday homes; but this will take a little time to ablish, and will oblige patients to answer questions ut their income. Some of the teaching hospitals are mselves paying for convalescent treatment in holiday nes, and this lead might possibly be followed by other pitals until something more satisfactory is arranged. e principles of prevention and reablement upheld by Act are contravened if some patients are charged for easonable and necessary period of recuperation while ers are not.

STREPTOMYCIN SUPPLIES

OR the past year the Emergency Bed Service (E.B.S.) London has acted as an admission bureau for cases tuberculous meningitis and miliary tuberculosis uiring streptomycin. This arrangement has worked l, and for some months the E.B.S. was able to find ed for every case found to be suitable for streptomycin tment. Unfortunately, however, since the number eds set aside in the selected hospitals for the official l of streptomycin was limited, and because of the g course of treatment necessary, in April of this year cases in the hands of the E.B.S. began to accumulate—which is highly undesirable in a disease where early treatment is essential. In the annual report of the King's Fund Sir Harold Wernher, chairman of the E.B.S. committee, says that during April 45 cases were awaiting admission, with little chance of finding a bed in time for treatment to be valuable. Lately this figure has fallen slightly to about 35—mostly children. It was generally understood that lack of dollars prevented any more streptomycin being imported, and that home production was unlikely to contribute significantly to our needs until the autumn. It was therefore a pleasant surprise when the Minister of Health, in reply to Parliamentary questions on July 14, made the following announcement:

> Streptomycin is not in short supply because of its cost in dollars at all. Production on quite a large scale over here has begun. Already, together with purchases still being made from the U.S.A., it is enough to cover all medical needs for which the use of the drug is so far reliably indicated—and shortly it should do so without any need for purchasing abroad. I am advised as to the purposes just mentioned by the Medical Research Council. There is still some limitation of suitably staffed beds and therefore some waiting-lists, but—now that I am in a position to do so, since 5th July—I am asking all regional hospital boards to arrange additional facilities wherever they can.

Immediately afterwards an official announcement was made that any hospital needing streptomycin for a patient with tuberculous meningitis or miliary tuberculosis would be able to obtain it by applying to the Supplies Division of the Ministry of Health. As a result the E.B.S. accumulation vanished overnight.

WORLD HEALTH ASSEMBLY

IN the weeks since its opening on June 24 [1] the World Health Assembly at Geneva has made slow but generally satisfactory progress, most of the work being done in the various committees. On the motion of Sir Wilson Jameson, for the United Kingdom, the United States delegation were admitted to full membership despite the reservations made by Congress in ratification. A more serious difficulty arose on July 10 when vigorous protests were made against the general committee's nominations of a "slate" of 18 members for the executive board, —to be accepted or rejected as a whole. The committee had evidently found it difficult to reconcile such factors as the claims of the Great Powers, the fact that only 8 countries in the American continent have so far ratified (compared with 24 in Europe), and the desire of the Russian group to be well represented. The committee's nominations, which were ultimately endorsed by the assembly on July 14 by 39 votes to 10, distribute seats as follows: United States, Mexico, Brazil; South Africa; Egypt, Iran; India, Ceylon; China, Australia; Norway, Netherlands, United Kingdom, France, U.S.S.R., Byelorussia, Poland, Yugoslavia. Despite grave doubts on various sides, the assembly has adopted a proposal that five regional offices should be established as soon as a majority of the countries proposed for each region decide that they want to have one. Thus the Alexandria bureau is likely to be recognised as the regional centre for the Near East, while the "Middle East" will probably have an office in Mysore. African and Far Eastern regions, and the integration of the Pan-American Sanitary Bureau as the regional office for the Western Hemisphere, may take more time, and the financial aspect of regionalisation has yet to be squarely faced.

As already recorded, the assembly has chosen Geneva as the permanent seat of the World Health Organisation. Next year's meeting of the assembly is to be held in Europe, and Dr. Melville Mackenzie last week conveyed a warm invitation from the British Government to make London the meeting-place.

---

[1] *Lancet*, July 3, p. 17.

whose oxygen requirements are greatest and whose function is associated with a highly concentrated filtrate of altered reaction. Thus it seems that the partial ischæmic and/or anæmic anoxæmic elements cannot be excluded in crush syndrome any more than in blackwater fever or mismatched transfusion.

The recent experimental work of BADENOCH and DARMADY[18] showed that tubular lesions morphologically and functionally closely comparable to those in human crush syndrome can be produced in rabbits by renal ischæmia only. In unilaterally nephrectomised rabbits the artery of the remaining kidney was severely constricted for 60, 90, or 120 minutes. The animals of the first group showed characteristic lesions in the ascending limb of Henle and in the distal convoluted tubule, namely degeneration and later repair with epithelial plications, and tubovenous herniations; they exhibited varying degrees of urea retention and survived for between 7 and 14 days (20%) or longer (80%). When severe renal ischæmia was maintained for 90 and 120 minutes the tu lesions were more extensive, more severe and acute and the mortality-rates (not surviving beyond 14 days) were 60% and 100% respectively. In similar experiments,[19] severe renal ischæmia and simultaneous hæmoglobinæmia resulted in an increase in the mortality-rates of the two shorter-period groups, indicating the summation of the ischæmic and athrocytic effects. These factors are not mutually exclusive but synergistic.

Of those who have drawn an analogy between the renal lesion of crush syndrome and that found after incompatible blood-transfusion, in blackwater fever, and in paroxysmal hæmoglobinuria and other conditions, some emphasise the pigment and athrocytic aspect to exclusion of the ischæmic and anæmic anoxæmic factors: it seems probable that all these factors are involved and that the part each plays depends on the nature of the primary or precipitating condition.

Annotations

COST OF MENTAL HEALTH

JUDGING by the spate of films, radio plays, and novels in which the blessed word "psychology" provides the background of the drama, the general public are now ripe for a little practical teaching on mental health. They have assimilated with unexpected enthusiasm the notion that more goes on in the mind than meets the conscious eye; and though they are perhaps more prone to attribute peculiar subconscious twinges to their neighbours than to themselves, they have now some inkling that people who behave obscurely, eccentrically, or even plain badly are not always wholly and consciously to blame. This is a great step forward from the days when the eccentric was a walking invitation to his neighbours to pelt him with mud or scorn him with hard words. But the conception is still intellectual rather than emotional. It is easy enough to say "poor feller" when the amnesic hero of a film reveals his mental anguish in appropriately moving gestures; much harder to bear at close quarters the difficult old aunt who hides rubbish in drawers and looks so odd to the people next door. Yet it is with the difficult aunt that the public need help—and with the convalescent but still psychotic brother returned from a mental hospital, the unlovable type of imbecile child, the depressed and weeping father, the anxious obsessional elderly spinster who worries her landlady, the paranoid kinsman who makes enemies for the whole family. These are the mental-health problems which face us in real life, and they are exceedingly common.

It is thus the more astonishing that the annual report of the National Association for Mental Health records on every other page the restrictions imposed by lack of funds. This association, incorporating the Central Association for Mental Welfare, the Child Guidance Council, and the National Council for Mental Hygiene, undertakes wide duties in aftercare, social case-work, problems connected with guardianship and licence, foster-home placement, care of epileptics, and many other activities, and also carries on research and provides homes and hostels for mental defectives and maladjusted children. The council of the association find there is a growing demand for talks and lectures on mental-health subjects, and that increasing numbers of candidates are coming forward for training in mental-health work. Group meetings for discussion and the study of mental-health questions are attended well by members of local associations. Yet "subscriptions and donations remain small," Dr. Kenneth Soddy, the medical director, reports, "and there is no indication that the work will readily command public support." Is this because the public in general have not yet been able—or perhaps have not been successfully encouraged—to link up their interest in "psychology" with the mental-health problems they encounter in their ordinary lives? Prof. Alexander Kennedy, speaking not long ago after a wireless programme which illustrated the life-history of a paranoid case, said the advantage of such broadcasts was the insight they gave into mental illness. Certainly the broadcast in question, "The Man Who Liked Clocks" excited sympathetic interest. It should be possible, in some of the health programmes, to give short accounts of typical case-histories of patients with neuroses and recovered psychoses, and to explain the help the association can give both to patients and to friends and relatives. Once these services are widely understood and recognised adequate funds should be forthcoming.

OUR HOSPITALS IN RETROSPECT

ONLY when very young do we fancy our generation's chances of putting some human institution right. Later we realise that building is perpetually going on, and that the most any one generation can do is to contribute—or drop—a few bricks. The story of our hospitals, told in the *Britain in Pictures* series by Mr. A. G. L. Ives, secretary of King Edward's Hospital Fund for London, is an outstanding example of this human technique. This year the contributions made industriously and half unconsciously since the time of Edward VI have grown together into an integral hospital service, and we may well sit back and regard it with astonishment for a few moments, as coral insects might on finding they had made an atoll. In the hands of Mr. Ives the story is never dull, for he draws on an extensive fund of knowledge, and like a good companion offers us in this review the rare and refreshing rather than the familiar and stale. Much that has gone before was better than the practice of today: thus in the sixteenth century, at the newly refounded St. Thomas's, it was customary for one of the almoners to attend at meal times to see that "rations were ample and properly cooked"; Thomas Guy originally intended that his hospital should provide for the chronic sick and t

ork—than the more placid long-distance man. The lue of glucose and alcohol is chiefly psychological. lcohol in moderate amounts with meals may help to ard off staleness. Though the first to suggest that ucose should be taken immediately before races, he w believes that its effect is due principally to the easant sweet taste.

Physiological research in the twelve years since the t Games has strengthened the hypothesis that in e production of energy carbohydrate, fat, and protein ally follow a common path; it is now virtually certain at these three main energy foods are partly or wholly terconvertible. Thus it seems that the athlete in ining will do well to follow his own likes and dis- es; in satisfying his appetite he will get the carbo- drate and proteins he requires. He need take no amin pills or glucose tablets, and he should drink ely—not necessarily avoiding alcohol with meals, ovided that the amount is moderate.

COST OF CONVALESCENCE

As things stand at the moment, some patients have pay for convalescent treatment while others get it e. There are three categories of convalescent homes: a relatively small number transferred to the National alth Service; (2) a few that successfully appealed ainst such transfer and were "disclaimed"; and a relatively large number remaining outside the service, ich the Ministry of Health classes as "holiday homes." ough the regional boards are required to pay for tients in transferred and disclaimed homes, they ve no power to pay for patients in holiday homes: d the methods of supporting hospital patients in this t and largest group still seem to be uncertain. The al authorities, it is true, have powers under section 28 the Act to pay for aftercare, and this is sometimes ken to include convalescence: but the idea is new, d though the authorities generally agree to it, it y be some time before any payments are actually de. Meanwhile, King Edward's Hospital Fund Emer- cy Bed Service, which has agreed to provide, on uest, information about vacancies in convalescent nes, finds that a curious situation is developing. All nes are fully booked, but the transferred and dis- imed homes have long waiting-lists, while waiting- s for the holiday homes are much shorter. It is arly only a matter of time before patients in holiday mes ask: "Why am I paying, here, when Mrs. So-and- was sent to a convalescent home for nothing?"

The regional boards are trying to arrange that the al authorities should meet the cost for patients sent holiday homes; but this will take a little time to ablish, and will oblige patients to answer questions ut their income. Some of the teaching hospitals are mselves paying for convalescent treatment in holiday nes, and this lead might possibly be followed by other pitals until something more satisfactory is arranged. e principles of prevention and reablement upheld by Act are contravened if some patients are charged for easonable and necessary period of recuperation while ers are not.

STREPTOMYCIN SUPPLIES

OR the past year the Emergency Bed Service (E.B.S.) ondon has acted as an admission bureau for cases tuberculous meningitis and miliary tuberculosis iring streptomycin. This arrangement has worked , and for some months the E.B.S. was able to find d for every case found to be suitable for streptomycin tment. Unfortunately, however, since the number eds set aside in the selected hospitals for the official l of streptomycin was limited, and because of the course of treatment necessary, in April of this year cases in the hands of the E.B.S. began to accumulate—which is highly undesirable in a disease where early treatment is essential. In the annual report of the King's Fund Sir Harold Wernher, chairman of the E.B.S. committee, says that during April 45 cases were awaiting admission, with little chance of finding a bed in time for treatment to be valuable. Lately this figure has fallen slightly to about 35—mostly children. It was generally understood that lack of dollars prevented any more streptomycin being imported, and that home production was unlikely to contribute significantly to our needs until the autumn. It was therefore a pleasant surprise when the Minister of Health, in reply to Parliamentary questions on July 14, made the following announcement:

> Streptomycin is not in short supply because of its cost in dollars at all. Production on quite a large scale over here has begun. Already, together with purchases still being made from the U.S.A., it is enough to cover all medical needs for which the use of the drug is so far reliably indicated—and shortly it should do so without any need for purchasing abroad. I am advised as to the purposes just mentioned by the Medical Research Council. There is still some limitation of suitably staffed beds and therefore some waiting-lists, but—now that I am in a position to do so, since 5th July—I am asking all regional hospital boards to arrange additional facilities wherever they can.

Immediately afterwards an official announcement was made that any hospital needing streptomycin for a patient with tuberculous meningitis or miliary tuberculosis would be able to obtain it by applying to the Supplies Division of the Ministry of Health. As a result the E.B.S. accumulation vanished overnight.

WORLD HEALTH ASSEMBLY

IN the weeks since its opening on June 24 [1] the World Health Assembly at Geneva has made slow but generally satisfactory progress, most of the work being done in the various committees. On the motion of Sir Wilson Jameson, for the United Kingdom, the United States delegation were admitted to full membership despite the reservations made by Congress in ratification. A more serious difficulty arose on July 10 when vigorous protests were made against the general committee's nominations of a "slate" of 18 members for the executive board,—to be accepted or rejected as a whole. The committee had evidently found it difficult to reconcile such factors as the claims of the Great Powers, the fact that only 8 countries in the American continent have so far ratified (compared with 24 in Europe), and the desire of the Russian group to be well represented. The committee's nominations, which were ultimately endorsed by the assembly on July 14 by 39 votes to 10, distribute seats as follows: United States, Mexico, Brazil; South Africa; Egypt, Iran; India, Ceylon; China, Australia; Norway, Netherlands, United Kingdom, France, U.S.S.R., Byelorussia, Poland, Yugoslavia. Despite grave doubts on various sides, the assembly has adopted a proposal that five regional offices should be established as soon as a majority of the countries proposed for each region decide that they want to have one. Thus the Alexandria bureau is likely to be recognised as the regional centre for the Near East, while the "Middle East" will probably have an office in Mysore. African and Far Eastern regions, and the integration of the Pan-American Sanitary Bureau as the regional office for the Western Hemisphere, may take more time, and the financial aspect of regionalisation has yet to be squarely faced.

As already recorded, the assembly has chosen Geneva as the permanent seat of the World Health Organisation. Next year's meeting of the assembly is to be held in Europe, and Dr. Melville Mackenzie last week conveyed a warm invitation from the British Government to make London the meeting-place.

whose oxygen requirements are greatest and whose function is associated with a highly concentrated filtrate of altered reaction. Thus it seems that the partial ischæmic and/or anæmic anoxæmic elements cannot be excluded in crush syndrome any more than in blackwater fever or mismatched transfusion.

The recent experimental work of BADENOCH and DARMADY[18] showed that tubular lesions morphologically and functionally closely comparable to those in human crush syndrome can be produced in rabbits by renal ischæmia only. In unilaterally nephrectomised rabbits the artery of the remaining kidney was severely constricted for 60, 90, or 120 minutes. The animals of the first group showed characteristic lesions in the ascending limb of Henle and in the distal convoluted tubule, namely degeneration and later repair with epithelial plications, and tubovenous herniations; they exhibited varying degrees of urea retention and survived for between 7 and 14 days (20%) or longer (80%). When severe renal ischæmia was maintained for 90 and 120 minutes the tu lesions were more extensive, more severe and and the mortality-rates (not surviving bey 14 days) were 60% and 100% respectively. similar experiments,[19] severe renal ischæmia simultaneous hæmoglobinæmia resulted in an inc in the mortality-rates of the two shorter-peri groups, indicating the summation of the isch and athrocytic effects. These factors are not mutu exclusive but synergistic.

Of those who have drawn an analogy between renal lesion of crush syndrome and that found aft incompatible blood-transfusion, in blackwater fev and in paroxysmal hæmoglobinuria and other con ditions, some emphasise the pigment and athrocyt aspect to exclusion of the ischæmic and an anoxæmic factors: it seems probable that all the factors are involved and that the part each play depends on the nature of the primary or precipitatin condition.

Annotations

COST OF MENTAL HEALTH

JUDGING by the spate of films, radio plays, and novels in which the blessed word "psychology" provides the background of the drama, the general public are now ripe for a little practical teaching on mental health. They have assimilated with unexpected enthusiasm the notion that more goes on in the mind than meets the conscious eye; and though they are perhaps more prone to attribute peculiar subconscious twinges to their neighbours than to themselves, they have now some inkling that people who behave obscurely, eccentrically, or even plain badly are not always wholly and consciously to blame. This is a great step forward from the days when the eccentric was a walking invitation to his neighbours to pelt him with mud or scorn him with hard words. But the conception is still intellectual rather than emotional. It is easy enough to say "poor feller" when the amnesic hero of a film reveals his mental anguish in appropriately moving gestures; much harder to bear at close quarters the difficult old aunt who hides rubbish in drawers and looks so odd to the people next door. Yet it is with the difficult aunt that the public need help—and with the convalescent but still psychotic brother returned from a mental hospital, the unlovable type of imbecile child, the depressed and weeping father, the anxious obsessional elderly spinster who worries her landlady, the paranoid kinsman who makes enemies for the whole family. These are the mental-health problems which face us in real life, and they are exceedingly common.

It is thus the more astonishing that the annual report of the National Association for Mental Health records on every other page the restrictions imposed by lack of funds. This association, incorporating the Central Association for Mental Welfare, the Child Guidance Council, and the National Council for Mental Hygiene, undertakes wide duties in aftercare, social case-work, problems connected with guardianship and licence, foster-home placement, care of epileptics, and many other activities, and also carries on research and provides homes and hostels for mental defectives and maladjusted children. The council of the association find there is a growing demand for talks and lectures on mental-health subjects, and that increasing numbers of candidates are coming forward for training in mental-health work. Group meetings for discussion and the study of mental-health questions are attended well by members of local associations. Yet "subscriptions and donations remain small," Dr. Kenneth Soddy, the medical director, reports, "and there is no indication that the work will readily command public support." Is this because the public in general have not yet been able—or perhaps have not been successfully encouraged—to link up their interest in "psychology" with the mental-health problems they encounter in their ordinary lives? Prof. Alexande Kennedy, speaking not long ago after a wireless pr gramme which illustrated the life-history of a para case, said the advantage of such broadcasts was insight they gave into mental illness. Certainly broadcast in question, "The Man Who Liked Clock excited sympathetic interest. It should be possible some of the health programmes, to give short accou of typical case-histories of patients with neuroses recovered psychoses, and to explain the help the association can give both to patients and to friends relatives. Once these services are widely understood and recognised adequate funds should be forthcoming.

OUR HOSPITALS IN RETROSPECT

ANSWERING A CALL

he service is now centred in the Ayrshire Central pital at Irvine. The team of two nowadays travels n 8 h.p. Morris or Ford car. This is an interesting sure of our present modest standards: Dr. Morris l a 21 h.p. Hillman, an easily recognisable car, which ld be stopped by a policeman with a message if a came through when he was out on less urgent duties. his account of the service he mentioned the need combining speed and caution in getting to cases. was also hoping to see the team of two expanded four—perhaps five. He would have liked to add a ior nurse, a chauffeur, and a universal donor—ugh he agreed that the chauffeur might combine last quality with the ability to drive a car. Modern nsfusion technique has made the donor unnecessary. l with a smaller car the chauffeur has been squeezed . The need for speed remains, however, and Dr. Soldenhoff urges doctors to send early when a patient leeding. He would like to see a conference over every ternal death, whether it happens in or out of hospital, which all interested should be present. This, he lieves, would help to prevent future tragedies.

Disabilities

9. INFANTILE PARALYSIS

I CONTRACTED infantile paralysis while serving with the rchant Navy in the Far East in 1939. In 1942 I was charged from hospital with complete paralysis of the leg, partial paralysis of the right leg, abdomen, and k, and diplopia in the left eye. I now wear a full-gth calliper with a corset-type spinal jacket and use o sticks to walk.

Disability is mainly in the eye of the beholder. The lexion I see when passing a shop window—the lurching t, the two sticks, the black eye-shield—is almost believable. In a mirror the sticks appear to be being ced on to the ground: it looks tremendously hard rk. But in fact it is not. To me, walking on the el is almost effortless, and I feel I am using my sticks y as many people swing their rolled umbrellas.

This misconception has a moral. Sometimes I have n disappointed that strangers do not share my husiasm for recovery. The mirror has told me why.

o the fit it is something of a paradox that disability, war, can bring new and unexpected opportunities self-development. We see different images of the e object. So it is not surprising that, on first acquain-ce, there is a gap between a disabled person's view is own disability and other people's view of it. The cessful disabled person is the one who narrows that gap eveloping unsuspected abilities.

here are two alternative pitfalls which await the nanently disabled. First, there is the obvious danger assively accepting disablement and so changing one's downwards, narrowing one's interests and perhaps pting lower employment to suit one's new condition. ndly, there is the not so obvious danger of refusing dmit one's disability. Dr. Hannan[1] referred to this as er compensation." If a disability is permanent e is nothing to be gained by denying facts, and indeed ong as one deludes oneself that the disability is only porary one is building on sand and will get no nearer ecoming a successful disabled person. As I see it, conquest of disability is the widening of one's rests and the raising of one's standard of life, despite physical handicap.

EARLY RECOVERY

ny success I have had in overcoming my disability be traced back to the fact that throughout my years in hospital I was never allowed to become tally sluggish. During the first 6 months, when I was either being moved from one Asiatic hospital to another or being shipped home, there was a continual change of surroundings which did much to prevent boredom. Once back in England and safely billeted in an E.M.S. ward there were fewer distractions. But there were compensations, not the least effective of which was meeting cases worse than myself. Any nodules of self-pity were soon dispersed by being opposite two cases of ankylosing spondylitis, lying on their beds as stiff as pokers from neck to heels. To see them happy, contented, and even occupied must have been a great boost to anyone's morale. It was impossible not to feel that if life held something for them it probably held a good deal for me.

I benefited too from the change from a private room to an open ward. Single rooms are pleasant enough, and I found the solitude and opportunity for meditation enjoyable. Nevertheless, by oneself one is inclined to lose touch with reality and even get fussy. An orthopædic ward full of long-term patients from Bermondsey and the Borough presents very different conditions. If my existence was more austere it was certainly more healthy psychologically. At all events I was living among real people, most of whom would, for economic reasons, regard a life of idleness—albeit enforced idleness—with abhorrence. I cannot emphasise too much the importance of living in a community whose members tacitly assume that they will return to some form of remunerative employment. It was, I think, because of this outlook that we were such a remarkably contented lot, and this in itself helped all of us along the road to recovery.

In addition to the normal therapies we were influenced for the better by two external considerations—the weather and the design of our hut. The hut was in an open field, with three or four double doors on each side, so it was comparatively easy to move the beds out on the grass on sunny days; and fortunately those two summers were particularly sunny. We thus benefited from the sunlight and fresh air as well as from the change of scene, which since the beds were not always placed in the same position was doubly varied. Altogether life was anything but stagnant, and it wasn't surprising that in a few months I began to develop the first compensation to disability—a satisfied outlook.

The next step in my mental rehabilitation came about quite by chance. One evening the ward sister asked me to lend her a ruler so that she could rule up the Report Book. Having nothing particular to do, I offered to do it for her. For the next year that, and later the weekly store sheets and nurses off-duty list, became my regular Saturday night work. It was astonishing how hard it was at first. The laboured care with which I measured the width of each column was almost laughable; I suppose a year in bed had dulled my powers of concentration. But it was a tonic and I think it provided something which occupational therapy, then in its infancy, lacks even today—a feeling of responsibility. However simple the job may seem now, it did not seem so elementary then, and I felt I was being relied upon to get it done. Come Saturday night, and whether I wanted to or not I had to get down to it. This compulsory disciplining of my mind produced the second necessity to fight disability—a constructive outlook.

No paragraph on recovery would be complete without reference to the Infantile Paralysis Fellowship, whose activities have persuaded many a disabled person that he will get a place in the sun.

INSTRUMENTS

I am, of course, completely dependent, for walking, on surgical appliances. The full-length calliper and spinal jacket are as necessary to me as trousers are in Oxford Street.

It may come as a surprise to many people that, after experiment, I have abandoned the bending calliper and

Special Articles

AN OBSTETRIC EMERGENCY SERVICE

The Ayrshire Emergency Domiciliary Service, with more than ten years' experience to its credit, is an example worth studying. It was founded in 1937 by Dr. W. I. C. Morris, then consultant obstetrician to the Ayrshire County Council, and operated from the Seafield Hospital. In a report[1] on the work of the service published in 1939, Dr. Morris noted that some 47% of the cases treated were operative emergencies, while 45% were cases of hæmorrhage. Nowadays cases needing operative help are fewer—presumably because they reach hospital earlier—while the treatment of cases of hæmorrhage has expanded greatly with improvements in the blood-transfusion services. The cases mainly treated today are postpartum hæmorrhage, retained placenta, and incomplete abortion.

EQUIPMENT

The original equipment consisted of an instrument bag, a canvas and leather holdall, two canvas containers for sterile drums, a flask of dextrose in normal saline, and a sphygmomanometer. The holdall contained various packets, in which were materials for dealing with different emergencies—preparation of vulva, forceps delivery, tears, craniotomy, and abortion.

Dr. R. de Soldenhoff, Dr. Morris's successor, has lately given a description of the service today, and of the equipment used.[2] He pays tribute to Dr. Morris's ingenuity in devising the original equipment: the only changes made have been those arising from the change in the character of cases dealt with. The modern equipment is as follows:

1. A bag containing drugs, anæsthetics, a hand centrifuge, antiseptics, syringes, and a head-light.
2. A sphygmomanometer.
3. A tripod stand with a T-bar to carry blood-transfusion bottles.
4. A box containing recipient and donor sets supplied by the West of Scotland Blood Transfusion Service.
5. A box containing blood, plasma, and bottles with citrate for donors.
6. Five small drums for high-pressure sterilising, containing: a cutting-down set for giving blood; spare dressings and uterine packs; gloves; caps, masks, and small towels; lithotomy sheet and towel clips.
7. A canvas bag with straps containing a preparation-of-vulva packet, rubber mackintosh, and rubber apron; a drip-saline packet, and a litre bottle of 10% glucose saline.
8. A canvas bag with straps containing one packet with material for suture of perineum or repair of cervix, and another packet with material for clearing out incomplete abortions.

THE SERVICE IN ACTION

Any obstetric emergency associated with hæmorrhage can be dealt with using this equipment. On receiving a call, Dr. de Soldenhoff or his assistant, and a house-surgeon, collect the equipment (which has already been sterilised) from the front hall of the hospital, pack it into the back of a car and go to the case. The interval between receiving a call and setting out is never more than ten minutes. No case of the emergency type is brought into hospital until the condition is sufficiently improved for the patient to stand the journey by ambulance. A blood-pressure below 90 mm. Hg systolic is looked upon as a bar to travel: when a case is to be moved the blood-pressure should be within the region of 100. The patients are mostly victims of severe hæmorrhage and have undergone the strain of delivery or obstetric interference; they do stand travelling well.

TRANSFUSION

All incomplete abortions of the emergency type dealt with in the home, as are retained placentæ postpartum hæmorrhage, great care being taken to av over-transfusing. Whenever possible, blood is plasma being given only at the start of treatment until blood is ready.

The patients are cross-matched and tested aga high-titre Rh-factor serum. This helps to eliminate number of Rh-negative cases, and—though not co pletely accurate—it picks out the majority of Rh-posit mothers and so is of use in emergency work. After t case has been dealt with a firm effort is made to tak pint of blood or more from the relatives, to replace blo given. This is sent the next day to the West of Scotla Blood Transfusion Service. Last year a total of 52 of blood and 38 pints of plasma were used in the em gency service. If, after the volume of blood lost has be partially replaced, the blood-pressure is still very l —say 70/40 mm. Hg—'Methedrine' is sometimes give 15 mg. intravenously and a further 15 mg. intramu cularly. The results have been impressive, in som cases, in restoring the blood-pressure, but methedri has not yet been used in enough cases to justify an statement as to its ultimate worth.

The danger of over-transfusion is always being stresse the team fully realise that, on occasion, patients ha been killed by too energetic replacement therapy an the giving of intravenous fluids too quickly. Once th patient's general appearance improves and the pulse i steady (even though the blood-pressure may not have reached 100 mm. Hg) she is given morphine and left to recover, since her blood-pressure will eventually reach normal.

Morphine, however, may also be given ove enthusiastically. Only enough should be given (D de Soldenhoff thinks) to dull pain and ease restless Larger doses depress the respiratory system, and the patients need all the oxygenation they can get. cases complicated by severe pain intravenous morp is beneficial, and has helped shocked patients dra tically. Where an anæsthetic is required, intraven thiopentone is used in minimal doses: more th 0·4 gramme is rarely needed and it is given very sl The patient is always brought to the best pos condition for any operative procedure, but time is n wasted where there is bleeding with a retained placen The team's first task is to control the hæmorrh

alking with sticks in slippery weather is an unpleasant
ness. But if you must go out when the pavements
icy, I can only say, don't put too much weight on
stick, don't hurry, and above all maintain an even
d. Change of speed is more likely than anything
to make you slip.

he lavatory and bathroom should be together for the
bled person, who can then wash before touching his
s.

RECREATION

ll work and no play makes disability a dull business.
I consider, though others may disagree, that the
ntial factor in recreation is participation. At Lords
t Wembley, where everyone is watching, being a
tator is all very well; but at the local tennis club,
re the play's the thing, it is not quite so good. To
mind, it is far better for a disabled person to spend
eisure hours painting, playing darts, learning bridge,
ven becoming the local tiddlywink champion than
nim to watch the local hockey club every Saturday.
he first case he will be taking an active part, not
in the play but also in the discussions and arguments
h follow the game and are as much recreation as
game itself. At the hockey club on the other hand,
e sole perennial and perhaps solitary spectator, he
be apart from the actual play, and though his
ions will be politely listened to he cannot hope to be
e same footing as the participants. Nor do I think
n experience that feeling of satisfied achievement
h is the prerogative of the player.

om my own experience boating has much to commend it. Once on board I can dispense with my sticks
gether, and with one hand on the gunwale or the
t I can clamber about, if not with agility, at least
sufficient speed to take a part in sailing the boat.
every form of exercise the difficulty is not so
with my leg as with my spinal jacket, which can
ly restrict my movements. Usually I take it off
boat and leave it off for about an hour. Moving
n much easier.

ave also become a keen gardener. Fortunately
re situated on light sandy soil, and I have found
by sitting on the ground and using a small fork
dig as deeply and nearly as quickly as my wife
uses an ordinary fork. With practice it has become
easy to shuffle about on my seat, and with the
ption of lawns and hedges I can look after most
s of the garden. Here again, in the interests of easy
, I remove my spinal jacket when sitting down.
of the great advantages that gardening holds for
with leg disabilities is that it gives you plenty
ercise without using your leg. When walking, the
of my good leg and the palms of my hands become
ed long before I feel that the whole of me has had
ient exercise.

MARRIAGE

marriage has been an essential ingredient in my
ery, and I should advise most other disabled men
e unto themselves a wife. No doubt there will be,
my case, a thousand and one good logical reasons
st such a course. But to admit them is to close
oor forever against a really normal life. Difficulties
must be; but they will be no more formidable
the many other difficulties experienced by fit
e in daily life. The human soul has something
resilience of a rubber ball—the greater the pressure
igher the bounce. To be the breadwinner for three
e has not been an insignificant part of my recovery,
he ownership of a house has, perhaps more than
ing else, produced a feeling of independence; and
he disabled the equation "independence=recovery"
ins a profound truth.

In England Now

A Running Commentary by Peripatetic Correspondents

THIS is the conference and convention season. Every Wednesday and Thursday you will find Euston and King's Cross crowded with ophthalmologists, pathologists, and what have you, each with a small bag (toothbrush, pyjamas, and a Penguin) and an air of pseudo-vacation. The surgeons, I am told, go by road. We enjoy going: we see many friends; we dine with moderate conviviality: and we hear some new ideas. (One learned man assured me that he went only to see in the flesh those whom he knew in print, so that he might assess their credibility—ipsa verba, "to make sure that they are liars.")

Let me tell those who have enjoyed the dinner (7s. 6d. including gratuity) at the scientific meeting of the Society of Experimental Omphaloscopists that in the matter and manner of a beano they have a lot to learn from the meetings of those concerned with the public health. These choose for their venue not some weary university town but a Resort with hotels de luxe and a mayor who gives a handsome if rather incoherent reception to the convention. Social events follow one another in lightning succession, and you will have the opportunity of enjoying a tour of a chocolate factory, a concert of light classical music in the Winter Garden, and a visit to Lover's Leap (admission 6d.) and the ruins of several medieval strongholds. It is true that some gentlemen make pronouncements connected with public health during the morning hours, but it is hard to finish breakfast by 9.30 A.M. when one has been dancing the evening before. We ought to know our fellow hygienists in other parts of the country, and what better opportunity could there be than the cocktail party given by the Aquaville Chamber of Trade? After all, our expenses are met by the ratepayers. (My own M.O.H. tells me that the care of his sweet-peas allows him no time for such gallivantings.)

* * *

In my student days, I should say less than one in seven budding doctors thought of specialising. But the other day I asked some final-year students about their choice of a career and 70% favoured specialism. *Spens agitat molem?*

* * *

There are troubles in the deep country which we as Londoners or near-Londoners once looked on as practically mythical. A hornets' nest is one of them. True, I have been stung by a hornet, but that was in the far South and I was competing with it for a bunch of grapes in the orchard. I can remember my noisy grief but not the application of any remedy, for I was but six, and I have a suspicion that it would be in accord with our easy-going Colonial ways to rely on the vis medicatrix naturæ. However, it appears that the hornet is a native inhabitant of England. Lately one has been prospecting in our garage, the vicar had one in his bathroom, we had another in our lavatory, and yet another flew with a purposeful air over our ripening raspberries. The question immediately arose from my alarmed household—how were hornet stings to be treated?

The popular belief is that three stings will kill a man, and five (or seven) a horse; but information on how to deal with a toxin so powerful as that of the hornet is alleged to be is entirely missing from my books. Thirty years ago a correspondent in the *Times*[1] first advocated using dilute acids (e.g., vinegar) for wasp-stings and dilute alkalis (e.g., ammonia) for bee-stings. *Martindale* gives a comprehensive list of remedies, including onion, but does not fit the remedy to the type of insect biting or stinging. Apparently both bee and wasp venoms are proteins, and the main troubles arise from allergic reactions or even anaphylactic shock if the sting gets into a vein.[2] *Webster's Dictionary* defines a hornet as a large wasp, so that local application of vinegar seems reasonable; but as the creature is said to be pugnacious, determined avoidance of its society seems highly desirable.

The vicar's treatment of his hornet seems to have been peculiarly British. He gave it several whiffs of 'Flit,' then felt sorry for it and let it out of the window.

2. Annotation, *Lancet*, 1941, ii, 319.

returned to the straight one. The reason, in a word, is "mobility." In office life it is important to be able to stand up and move about without having first to push a calliper into its locking position. "Only a matter of a few seconds," you may say. Maybe, but one does not want to be a second behind other people, and when one is also wearing a spinal jacket straightening a calliper may well take two or three seconds. Similarly in a crowded bus or train, with several people standing there is not always room to straighten a calliper without asking them to move.

Originally I had the Thomas-splint type with a complete ring at the top. This ring, in conjunction with my paralysed hip, knee, and ankle made it difficult —especially with trousers—to put the calliper on by myself. My present calliper has a half ring and strap, and is much easier to put on and off.

Regarding footwear, at first I bought the ordinary mass-produced medium-priced shoes which most people wear, and I must admit they seemed to meet my needs. But two years ago, as an experiment, I went to a firm of shoe manufacturers and had a pair made. They were a great success. More than anything else they seemed to enable me to balance better. With them, walking for a few yards with one stick, and taking a single step stickless, is not only possible but fairly easy.

Fortunately I could dispense with a wheel-chair soon after arriving home—but not before I had discovered that wheel-chairs which seem admirable in hospital are often not so suitable for the outer world. Their main defect is usually unwieldiness. The large comfortable folding chair is often difficult for a woman to heave on and off the back of a car. A friend of mine recently purchased from Resilco Ltd., of Hammersmith, a new type of light-weight chair which folds about a vertical rather than a horizontal axis. The ordinary flat seat can be lifted out and this allows the chair to fold up into a straight line, as it were, with the four wheels also in a straight line and still on the ground. It is quite easy for people of no great strength to move this chair about and lift it when necessary on to the back of a car.

RE-EMPLOYMENT

For the permanently disabled, work, not time, is the great healer; but it must be productive work, in which the disabled person is interested and which—more important still—he does not feel to be below his ability. Employment for employment's sake may come very near to self-imposed slavery. If work ceases to be a vocation and becomes a mere task it loses much of its value as a mental stimulus. When I started work again as a £3-a-week clerk it was not a pleasant experience. Any joy I might have felt at being back in employment was more than cancelled out by the apparent narrowness of the future and the not infrequent comments of one's acquaintances that one was "lucky to get a job at all." The day-dreams of hospital were, it seemed, to remain just day-dreams.

But even though the work was depressing, it was, when seen in the right perspective, as necessary as any treatment I had received. Though I did not realise it at the time, the important thing was that I had a foothold on the ladder of employment. Fortunately for me there was a war on, so the labour market acted in my favour. Soon I changed my job and later changed again and then again, and each change brought me an improved position. Several of my friends, so far from hailing each move as a step forward, regarded them as a foolish and unwarranted jettisoning of security. But on looking back I can see that, whatever the opinions of others, each change upwards strengthened my confidence, and this in turn was the best service I could do myself.

When later I purchased a car this enabled me to widen my activities. By the time the V1's arrived I was touring A.A. gun sites in south-east Essex as a lecturer for the Army Education Service. For the time I felt really independent. On the gun sites no- appeared to be at all astonished that I walked on st or that I sometimes needed assistance up steps I in fact, being cured of any disability complex I have possessed, not so much by my own efforts as b the attitude of others.

The unusual and not always consistent form employment I have chosen have justified themselves b results. The Army lecturing led indirectly to broadcast talks, and later to the writing of scripts; my chang in office life have at last resulted in my reaching th administrative level. I am still only 28 and it does n necessarily follow that I shall always be as succes nevertheless, I think there is enough evidence to convin other disabled people, and also those concerned their welfare, that security of employment is not ever thing. Taken too far it may lead to a rut of pleas appearance but deadening prospect. However, the important thing is to get a disabled person into a job and then encourage his ambitions.

TRAVEL

A person's success in overcoming his disability will, in the long run, depend on his ability to get about Whether he does it by wheel-chair, spinal carriage, private car, or public bus does not matter. But whether it is for employment or enjoyment, travel he must, and the nearer he can get to normal modes of transport the less unusual he will be considered by other people.

Unfortunately the design of buses is not always helpful. I rarely sit down in an M. & D. bus without scraping the shins of my callipered leg on the seat in front; and in most motor coaches it's impossible to stick a straight leg under the seat in front—one puts it in the gangway and hopes for an ob conductor and a rigid enforcement of the no-standing In contrast, all the modern types of London Tran Executive buses allow sufficient clearance for a stiff le pass under the seat in front. In a less bothering w the same applies to railway carriages, where the se opposite are sometimes too deep to allow a stiff leg pass underneath. A great help for boarding tr are the two vertical rails *inside* the door, as fitted some of the new Southern Region coaches.

On an average I travel on ten trains and twenty b each week. The only difficult part is getting on a off, and practice has made this much easier. The dr is to hold both sticks in your right hand, grasping the around the neck with the thumb and forefinger, so th your left hand is completely free and your right han almost so. One hand rail can then be grasped in eac hand and the right (fairly good) leg can be got on th platform and the other leg swung up. The right l acts as fulcrum with the arms and body as a lev This method saves any upward strain or pull, and b using the window-ledge of the open carriage door ins of the second hand-rail, can be applied to trains.

Experience has taught me that for coming do is a mistake to imitate the sideways method of able-bodied. The forwards position is safer, for wi sticks between your right thumb and forefinger, hands can be used for sliding down the rails, the adv of this being that if the vehicle unexpectedly pic speed one can, by gripping hard and pushing scramble back on the platform again.

Crossing roads, which may take anything from 1 30 seconds, is not a hazardous business. With little ch of success, there is no temptation to try a risky in the face of oncoming traffic. But once one has st across one should keep going—even in the face of app danger. No-one will wilfully run you over, and to will only confuse the drivers. Make your intenti clear by continuing your way and it is unlikely you will come to any harm.

alking with sticks in slippery weather is an unpleasant ness. But if you must go out when the pavements icy, I can only say, don't put too much weight on stick, don't hurry, and above all maintain an even d. Change of speed is more likely than anything to make you slip.

ne lavatory and bathroom should be together for the bled person, who can then wash before touching his s.

RECREATION

l work and no play makes disability a dull business. I consider, though others may disagree, that the itial factor in recreation is participation. At Lords t Wembley, where everyone is watching, being a tator is all very well; but at the local tennis club, e the play's the thing, it is not quite so good. To mind, it is far better for a disabled person to spend eisure hours painting, playing darts, learning bridge, ven becoming the local tiddlywink champion than im to watch the local hockey club every Saturday. he first case he will be taking an active part, not in the play but also in the discussions and arguments h follow the game and are as much recreation as game itself. At the hockey club on the other hand, ne sole perennial and perhaps solitary spectator, he be apart from the actual play, and though his ions will be politely listened to he cannot hope to be ne same footing as the participants. Nor do I think n experience that feeling of satisfied achievement h is the prerogative of the player.

om my own experience boating has much to commd it. Once on board I can dispense with my sticks gether, and with one hand on the gunwale or the rt I can clamber about, if not with agility, at least sufficient speed to take a part in sailing the boat. n every form of exercise the difficulty is not so h with my leg as with my spinal jacket, which can rely restrict my movements. Usually I take it off ne boat and leave it off for about an hour. Moving en much easier.

have also become a keen gardener. Fortunately e situated on light sandy soil, and I have found by sitting on the ground and using a small fork dig as deeply and nearly as quickly as my wife ises an ordinary fork. With practice it has become easy to shuffle about on my seat, and with the tion of lawns and hedges I can look after most of the garden. Here again, in the interests of easy , I remove my spinal jacket when sitting down. of the great advantages that gardening holds for with leg disabilities is that it gives you plenty ercise without using your leg. When walking, the of my good leg and the palms of my hands become ied long before I feel that the whole of me has had ient exercise.

MARRIAGE

marriage has been an essential ingredient in my ery, and I should advise most other disabled men ke unto themselves a wife. No doubt there will be, my case, a thousand and one good logical reasons ist such a course. But to admit them is to close oor forever against a really normal life. Difficulties must be; but they will be no more formidable the many other difficulties experienced by fit le in daily life. The human soul has something resilience of a rubber ball—the greater the pressure igher the bounce. To be the breadwinner for three e has not been an insignificant part of my recovery, the ownership of a house has, perhaps more than ing else, produced a feeling of independence; and he disabled the equation "independence=recovery" ins a profound truth.

In England Now

A Running Commentary by Peripatetic Correspondents

THIS is the conference and convention season. Every Wednesday and Thursday you will find Euston and King's Cross crowded with ophthalmologists, pathologists, and what have you, each with a small bag (toothbrush, pyjamas, and a Penguin) and an air of pseudo-vacation. The surgeons, I am told, go by road. We enjoy going; we see many friends; we dine with moderate conviviality; and we hear some new ideas. (One learned man assured me that he went only to see in the flesh those whom he knew in print, so that he might assess their credibility —ipsa verba, "to make sure that they are liars.")

Let me tell those who have enjoyed the dinner (7*s.* 6*d.* including gratuity) at the scientific meeting of the Society of Experimental Omphaloscopists that in the matter and manner of a beano they have a lot to learn from the meetings of those concerned with the public health. These choose for their venue not some weary university town but a Resort with hotels de luxe and a mayor who gives a handsome if rather incoherent reception to the convention. Social events follow one another in lightning succession, and you will have the opportunity of enjoying a tour of a chocolate factory, a concert of light classical music in the Winter Garden, and a visit to Lover's Leap (admission 6*d.*) and the ruins of several medieval strongholds. It is true that some gentlemen make pronouncements connected with public health during the morning hours, but it is hard to finish breakfast by 9.30 A.M. when one has been dancing the evening before. We ought to know our fellow hygienists in other parts of the country, and what better opportunity could there be than the cocktail party given by the Aquaville Chamber of Trade? After all, our expenses are met by the ratepayers. (My own M.O.H. tells me that the care of his sweet-peas allows him no time for such gallivantings.)

* * *

In my student days, I should say less than one in seven budding doctors thought of specialising. But the other day I asked some final-year students about their choice of a career and 70% favoured specialism. *Spens agitat molem?*

2. Annotation, *Lancet*, 1941, ii, 319.

The latest development is that the rural district council's rat-catcher has called, a large, fresh-faced man who shook his head when I asked whether the council would deal with a hornets' nest, when and if found. As a private citizen, though, he had dealt with one of his own, and he described with gusto how he did it. He arranged a box to stand a few inches below the nest—as large as the bucket my daily help, an interested listener, was holding. On the box he placed a rag soaked with "the stuff"—i.e., cyanide. Next day every hornet was dead. Feeling sure that I should be dead too if I attempted these manœuvres, I said that my husband was in poor health and could not be asked to do such things, and it did not seem quite the job for me. He suggested kindly that I could fix the rag on the end of a long stick, soak it in "the stuff," and hold it to the entrance of the nest until they were all killed. This seemed even more hazardous. It was an impasse and the rat-catcher was regretful. "Fleas?" he asked hopefully. I repudiated fleas. "Bugs? Blackbeetles?" He was lyrical over the number of blackbeetles he had lately killed. But I was firm that my only pests were hornets, and he left.

I forgot to mention the adder which lives in the corner of the garden near the garage, and which I strongly suspect of having bitten the cat. My rat-catching friend would probably have advised me to catch it by the neck and nip off its head with a quick flick of my teeth.

The differential diagnosis of "numismatist's thumb" (described in this column on July 17, p. 118) is obviously from "miller's thumb," a well-known occupational trauma familiar to Chaucer:

> "The Miller was a stout carl for the nones . . .
> Wel coude he stelen corn and tollen thryes:
> And yet he hadde a thombe of gold, pardee."

The allusion is to the acquisition by the miller of a smooth, broad, and rounded terminal phalanx to his pollex through the constant habit of applying it to the meal-spout to test the meal by rubbing it between fingers and thumb. By seeing that his meal was properly ground the miller was likely to make more profit—hence a "golden" thumb.

* * *

Writing a book is difficult enough but procuring the photographs with which to illustrate it presents frustrations and disappointments which are hard to bear. The infinite trouble and the large element of chance required to gather the patient, the photographer, and the lesions to be recorded together at any one time almost make one regret the old days when a drawing had to suffice, for this could be attempted unaided and the indifferent results handed at one's leisure to a proper artist for improvement.

Tonight a colleague excitedly brought me a specimen glass with its contents still warm to demonstrate a large object like a herring-roe vertically suspended in a hazy urine. It is many years since I last saw a complete vesicular cast, so putting the precious object in a place of safety, dropping my pen, and even leaving my pipe behind, I rushed off to find the photographer. Being at that twilight time when those engaged in more respectable occupations are buying their evening papers and making for home, I realised that this might be a difficult task. However, after many false hopes he was run to earth in the animal house, and all was tied up and arrangements completed for the picture to be made within the hour.

I spent a few minutes in admiring some golden hamsters of which the photographer was particularly proud—entertaining little fellows with large cheek pouches in which their recent meal could easily be palpated. Then, returning to the clinic, I was horrified to find that the precious cast could not even be classified as a thread but had melted away to leave just one more "urine: hazy in the first glass."

* * *

The recent headline, "A Meeting of Child Psychiatrists," conjures up in my mind a picture of a group of infant prodigies, their bulging brows wrinkled as they dogmatise over Freud. And talking about misleading titles, as a student my college boasted a Small Bore Club—I hate to think what its members have become by now.

Letters to the Editor

CARS FOR DOCTORS

SIR,—In his letter last week Dr. Boucher raises question of doctors having absolute priority for delivery. The reasons why this has not been are as follows:

1. If the whole medical profession had new cars, would absorb very nearly the whole of the home quota new cars for one year.

2. Human nature being what it is, and the secon prices of one-year-old cars being what they are, the t tion would be for every doctor to claim absolute and renew his car every year. This would mean that would be practically no cars for other essential users.

With regard to cases of genuine need, where doctor really has not got a serviceable car, then retail trade is doing its best to advance delivery to really early date. In such cases a high degree preference is given. A difference of opinion often as to what is a serviceable car. In some instances wh I have come across, the dealer claims with justice t the car regarded by the doctor as unserviceable with a little attention, easily run perhaps tens of thou more miles. We leave these cases to be settled betw the local dealer and the doctor concerned.

BEDS FOR TUBERCULOSIS

SIR,—In his article of May 8, Dr. Bentley, insp by visits to Swiss sanatoria, advocates the adoption a less rigid régime of bed rest in British institut He hopes in this way to alleviate the gloomy outlook f thousands of patients waiting in vain for admission sanatoria, where wards have been closed because of shortage of nurses.

Having been trained in very strict principles of rest and ample and efficient nursing while work a municipal institution in England during the la I had to face quite a different situation when I to my native country and took up work in a m institution here.

For 300 patients there were 28 nurses (most of them fully trained), including theatre staff and others not w in the wards. There was no matron, no assistant mat no senior sister, and no night superintendent or night si and I found the régime very lax. I admit to a long fi despondency over this appalling state of affairs. I de that I should have either to lower my own standards considerably, or to try to make the best of existing condi I decided on the latter course, and after a few months' str (aided by 3 or 4, mostly very junior, medical officers managed to introduce and maintain a régime which inc a fair amount of *collapse therapy* and major thoracic sur falling not very far short of that practised in most sa institutions in Britain. Needless to say, the disease in r of our patients was far advanced; and these had to be on very strict bed rest. The standard of nursing wa course, far from ideal.

After two years in this environment I found m placed in charge of a sanatorium in the country 14 nurses (only 2 fully trained) for 310 patients.

The patients were very much of the same type as t the hospital, but the proportion of really advanced ca somewhat lower. Again there was no matron o sister, and no night supervising staff (the night staff c of 5 nurses). The total of 14 nurses includes 4 serving operating-theatres, &c. Fortunately, there was an enth team of 3 experienced doctors, later increased to 5, inc 2 with excellent war-time experience in Britain.

While not claiming to have a model establishment succeeded in introducing a fairly strict régime of bed rest and exercise, including modest attempts at reha tion by graded work. The nursing staff are not overw in fact about a quarter of them are ex-patients. Again standard of nursing is not ideal, for there is precious blanket-bathing, treatment of pressure-points, or items of good classical *nursing*; but the bedridden pat are fairly well looked after, and the nursing in the th ty unit (12 beds) is good, although done by only 1 sister 1 other to help in the mornings.

out a quarter to a third of the patients are on a ified régime of more or less strict bed rest (stages 1–3); emainder (stages 4–6) are on bed rest for 6, 4½, and ours, respectively, in the daytime. There is one mediate stage—3A—which incorporates patients are on bed rest all day but are allowed to go to lavatory, wash in the bathroom, and take their ls in the common dining-room. Stage 1 is "absolute ," but with the existing staff we can afford to enforce in only a few special cases. All patients from e 4 upwards make their own beds, except for turning mattresses, and are on graded exercise. Some ents in stages 5 and 6 help to serve meals to their idden fellow patients, since domestic staff is also short; others help with the work in the vegetable len, workshops, offices, and laboratory. Quite a members of the administrative and maintenance are ex-patients.

ter induction of artificial pneumothorax patients are kept trict bed rest for 3 days, and then on modified bed rest ges 3 and 4) for a variable time; we are trying to keep all patients under institutional control for as long as feasible. r thoracoplasty patients are kept on almost absolute rest for about 5 days; then they are allowed to get up ne lavatory but continue to wash and feed in bed for 2–3 ks; after that they are kept on modified bed rest (stages 3 3A) for about 2–3 months, and on stage 4 for at least her 3 months, when they are put on graded exercise; im to keep them in the sanatorium for about one year operation. They are doing well on this routine, and have had remarkably few postoperative complications. usual operation is extrafascial thoracoplasty with apico- ; and, although we can afford very little in the way of siotherapy, the cosmetic and functional results are sfactory.

Ve have become much more liberal than formerly he number of patients who, while otherwise on bed , are allowed to get up to the lavatory and the bath- m. They are none the worse for this; and, as usually pens, morale has risen when the use of these amenities been permitted. Temperatures are taken and rded by the patients themselves, except for those of ients on very strict bed rest; while admitting this ot an ideal practice, we find that it is a workable promise.

certainly do not advocate the abolition of such l-tried lines of treatment as are practised in most ish institutions; nor would I suggest the almost bulatory treatment which is adopted at some places the Continent; but, with Dr. Bentley, I venture to gest that to meet the present difficult situation it ht be worth considering some relaxation of the very ct sanatorium routine, while maintaining the essential ures of bed rest, even if somewhat modified. I self look forward to the time when I shall work with "few" nurses as my more fortunate British colleagues e at present.

natorium U.S.N.P., Prosečnice nad Sázavou, Czechoslovakia.

Medical Director.

POSTCRICOID PHARYNGO-ŒSOPHAGEAL PERFORATION

IR,—Mr. Goligher is to be congratulated on his uable article in your issue of June 26, and on the py result in his 2nd case which was treated by nediate suture.

he second type of injury, which is probably less ommon, deserves emphasis because the pathological esses which are set up will often kill the patient as surely unless active measures are taken. This e of injury is illustrated by the following case.

man, aged 58, was admitted to Hammersmith Hospital Iay, 1941, with a long history of peptic ulceration. In course of investigation, gastroscopy was carried out by xpert, with local anæsthesia. The examination was made out difficulty and the patient made no complaint at time, although subsequently he said that his throat never been quite comfortable after the examination, swallowing was painful.

On the 4th day after the gastroscopy I saw the patient who was then complaining of tenderness in the lower part of the neck and a sore throat. On examination there was fulness at the lower part of the neck, and Pilcher's sign was positive. Retropharyngeal cellulitis with possible abscess was diagnosed and the chemotherapy then available was administered. His evening temperature was 101°F. On the 5th day the symptoms were rather worse. X-ray examination showed that the trachea was displaced forwards with posterior deformity; and translucent areas were present, indicating a collection of gas. A barium swallow showed partial obstruction. I came to the conclusion that the patient was suffering from a retro-œsophageal abscess, which should be drained.

Under general anæsthesia I made a transverse incision just above the clavicle, dividing the anterior part of the sternomastoid. The incision was deepened by blunt dissection, and in the retro-œsophageal cellular tissue an abscess was found, which contained gas and about 1 oz. of thin, foul-smelling pus. Sulphathiazole was dusted into the cavity, which was drained. A temporary gastrostomy was carried out. Culture of the pus showed *Streptococcus viridans* and diphtheroids.

Recovery was rapid: 9 days later the patient was swallowing normally, and 3 weeks after the drainage of the abscess I was able to carry out a partial gastrectomy. Convalescence was uninterrupted and the patient has remained well. An account of this case has been given by Grey Turner.[1]

The site of injury in this case was the same as in those described by Mr. Goligher; it may be, however, that in this type the harm is done not during the introduction of the instrument but through pressure during the subsequent examination. This danger is likely to arise if the examination is unduly prolonged in order to let several onlookers look down the instrument.

AN INTERNATIONAL STANDARD FOR STRETCHERS

SIR,—In the early days of the "Geneva Committee for Aid to the Wounded," the historic forerunner of the International Red Cross Committee, its founders emphasised the importance of the exchange of ideas, and of coöperation with the medical services of the various Powers. Henri Dunant, in particular, was much concerned about improvement in the means of transport of the wounded, the "universal" adoption of approved methods of treatment, and the institution of a "veritable museum" of military equipment.

A definite proposal for the general use of a stretcher of standard dimensions was made by Colonel van Baumberghen at the International Congress of Hygiene held in Berlin in 1907; but this proposal does not seem to have been followed by any immediate action. During the war of 1914–18 the diversity of types of stretcher in use by the various Powers came into distressing prominence. The measurements of French, British, American, and German stretchers differed so much that each stretcher was suited for transport only in an ambulance of corresponding national origin. Thus the wounded had at times to be transferred from one stretcher to another—a process inevitably painful, often dangerous, and always involving loss of time. As the French General Marotte remarked, "Never have the differences in the standard of equipment been so conspicuous and so prejudicial to the interests of the wounded." Even during hostilities conferences were held, including representatives of both sides, to try to reach some degree of uniformity in means of transport for the wounded, but with no success.

In 1921 at the 10th International Red Cross Conference, the first to be held after the war, Senator Ciraolo (Italy), president of the International Relief Union, pleaded for the adoption of a uniform standard of equipment by the different national red-cross societies, to facilitate collaboration in relief operations in the case of civil disasters. At the 12th International Red Cross Conference, held in Geneva in 1925, the president, Dr. Reverdin, said: "It is of the utmost importance for the wounded that the dimensions of all stretchers should permit of their adaptation to every type of carrying fitment and vice versa." A standard of dimensions, recommended by the commission, was adopted by the Red Cross Conference held at the Hague in 1928, subsequently modified by the Brussels Conference in 1930, and finally approved by the Tokio Conference of 1934. This model, however, did not win the approval of the various national medical services, and the outbreak of the war of 1939–45 found us still without an international standard of stretchers.

---

[1] Turner, G. G. Injuries and Diseases of the Œsophagus. London, 1946.

Civil defence against air-raids even added to the number of different types of stretcher. In England passive defence was undertaken by the specially created Air Raid Precautions Department of the Home Office, which used a rigid stretcher with the poles consisting of cast-iron tubing and the beds of iron-wire mesh. The all-over dimensions of the British Army stretcher were adopted, but the feet, consisting simply of downward salients on the poles, were too wide for the grooves in Army ambulances. Of the three main types of stretcher in use in England—British, American, and A.R.P.—none were interchangeable. Ultimately a simple adaptation of the width of the A.R.P. stretcher-racks permitted the carriage of both American and British Army stretchers in A.R.P. ambulances. An awkward feature of all three types was the length of the rigid poles, which prevented their introduction into most hospital lifts.

It is obvious that a stretcher of standard dimensions could meet most, if not all, occasions, both civil and military; indeed the argument in favour of a universal type applies not only to armies but also to civil institutions and voluntary organisations. The outbreak of the second world war called a halt to the activities of the standardisation commission of the International Red Cross; but it is hoped that, in view of the first post-war International Red Cross Conference due to be held in Stockholm next autumn, the commission will be given a new lease of life and will this time attain success.

Geneva. R. T. WELLS.

CHARMS

SIR,—Reading again the history of medicine the other day, I came across the following cure for mental illness, popularly prescribed by doctors in the Dark Ages: "Take clove wort and wreathe it with a red thread about the man's neck when the moon is on the wane in April or October; soon he will be healed." In view of Dr. Inman's successes with the burial of a sliced potato in the backyard by the light of the full moon, reported in your issue of July 10, I am wondering whether a revival of the older remedies is not indicated! The opinions of other psychiatrists are solicited.

Park Prewett Hospital,
Basingstoke.

I. ATKIN
Physician Superintendent.

SIR,—Dr. Inman's wart stories (July 10) provide good dramatic reading. That is why they continue to be interesting at each of their periodical revivals. Heaven knows how often one has read similar descriptions.

But Dr. Inman seems to go out of his way to invest his particular ritualistic form of treatment with an atmosphere of mystery and superstition. Mystery there is, in the sense of an unsolved problem as to the psychodynamics of warts and their disappearance under different modes of suggestion. If, however, Dr. Inman means that his treatment is a method of suggestion, why does he not make this evident? Is "charming" a wart a clearer or more instructive phrase? Allowing for the indefiniteness of the conception of suggestion, the use of the word does at least leave the problem a psychological one. He surely *cannot* mean more, since his knowledge (as distinct from speculation, which may, admittedly, be true) of the pathogenics and pathoplastics of the cases described remained exactly the same after he had "cured" them as before. In other words he knew as little about them after his successful treatment as he did before. Or does he, in fact, mean more? Is he implying that by his ritual he called in (or out) white and friendly spirits to help him? He may have forgotten that when Glendower declared he could call spirits from the vasty deep, Hotspur replied: "Why, so can I, or so can any man; but will they come when you do call for them?"

I should be interested, furthermore, to learn if Dr. Inman considers he has done the small boy of 8 any psychological harm when he told him to steal the and, after touching the warts with it, to bury i the backyard (with superstitious solemnity) by the of the full moon—the whole hocus-pocus to be out with the greatest secrecy? And how did a boy of 8 manage to do all this without his m becoming aware of it? Was he told to get up out of in the dead of night and creep into the backyard?

If Dr. Inman believes that it is desirable that wor in the subject should help to get psychology on t proper scientific plane, I suggest that his approach the wrong one. If he feels he must use potatoes saliva (perhaps he has delicately refrained from tioning other organic reagents), he might at least w out a technique that does not encourage a belief superstition and animism.

London, W.1. FREDERICK DILLO

TROTTER'S TREATMENT OF EPISTAXIS

SIR,—An anonymous past pupil of mine has recen thanked me in the *Guy's Hospital Gazette* for teac him Trotter's method of treating nose-bleed and "I have never heard of it elsewhere. Probably t well-known." This last statement is, I believe, incorrec for I have never met one of my colleagues who has u it, nor a student of any of them to whom it has taught.

I tumbled on Trotter's treatment of epistaxis in th sitting-room of an East-End doctor where I was waitin while he attended to one or two patients before going t a consultation with him. I picked up the current numb of the *Medical World* (Oct. 6, 1933) and started to rea an address on Emergency by Trotter that the editor had wisely reprinted from the *University College Hospita Magazine*. In it was incorporated his treatment o epistaxis, which impressed me at once. This addre has been given first place in the collection of Trotter papers by his son (Oxford University Press, 1941). H is the passage:

> "Prop the patient well up with a comfortable incl to one side, arrange a large pad of wool for him to into, put a dental prop between the teeth, *forbid breathe through the nose or to swallow*, and give a sub dose of morphia."

My first case was a doctor's elderly brother. I no dental prop; but there was a wine-cork in the h I have used a wine-cork—or one from a large medi bottle—ever since. You cannot swallow without shutt the mouth, but blood or mucus coming into the pha from the nose sets up the reflex when it touches t upper surface of the soft palate. If the patient is the right position with the nares lower than the cha this does not happen. The blood runs into the "la pad of wool."

I have never known this treatment of severe epista to fail except in the hands of house-surgeons who li "doing things." Trotter says "supposing you wis make a serious attempt in such a case to avoid t recognised but odious alternative of plugging the nose but there are some persons who really enjoy perform this "odious alternative," with the result that t do not pay enough attention to the position of the to the adjustment of the cork, and, above all, to "comfortable inclination"; then the treatment and they have an excuse to plug.

My greatest triumph was at St. James Hospital, Balham late Dr. W. L. MacCormac came to me, just as I was about a man who had been thrice transfused. He su *that I should perform an operation described* by in which the antrum was opened and then a counter made in its posterolateral wall through which the term of the internal maxillary artery was ligatured. I coul imagine myself doing such a thing; and to gain time whether they had tried Trotter's treatment. He did not it. By that time we had reached the man. He looke I told Dr. MacCormac that I was busy that afternoon could return at 5.30. In the meantime I thought it w trying Trotter's treatment; so we set about instituti and I went away leaving a telephone number in case th got worse. Actually I had nothing to do that day. I my consulting-room working at my income-tax retur 4.30 when I rang up the hospital. The bleeding had sto

;ave another telephone number and went and sat in my ringing up again before going home. The bleeding recurred.

ortly after reading that address I met Mr. Trotter poke to him about it. He went as near to registering ement as I have ever seen him do. He told me ad tried it on himself when his nose bled in an k of influenza. Fortunately, he said, his wife was out could do what he wanted instead of having to send colleague. He had thought the treatment out some before, and so he went to the closet and stood over an in the desired position and the bleeding stopped ice.

went on to tell me the rationale of the treatment. pends on the adhesion of the clot to the vessel wall. veins of the nose (the bleeding is usually, if not ys, venous) all stream back to pass through the iopalatine foramen; and as they do so they are d in grooves on the medial aspect of the turbinal s, with the result that if there is any tug on them is exerted on the free-side of the vessel which is not aced from its bony bed. Therefore such a tug pulls vessel wall from the underlying clot while this is in ss of becoming adherent. The clot becomes detached the bleeding recurs. The sphenopalatine foramen ust above and behind the hinder end of the middle nal. It is therefore at the junction of the nose and pharynx. Every time the soft palate goes up there initial negative pressure before it descends again, his produces the tug on the veins as they converge on phenopalatine foramen. Inhibit movements of the e and you stop this tug. Thus the clot can become ent and the bleeding ceases.

is is hard to put into writing, but it was as clear as ght when Trotter spoke it.

idon, W.1. T. B. LAYTON.

THE ROYAL COLLEGE OF SURGEONS

R,—Lord Webb-Johnson's reply in your issue of 3 ignores the essential point in our previous letter— ely, his suppression from the medical profession of esolutions passed at the fellows' meeting on April 28. suppression is maintained in Lord Webb-Johnson's r, in which, while mentioning the second and third utions, he does not disclose their nature.

ALEX. E. ROCHE
W. ETHERINGTON WILSON.

VENEREAL DISEASE

R,—In his letter in your last issue, Lord Horder is less o date than usual. He refers to the appreciable ase in syphilis and gonorrhœa reported for the 1945, but his purpose would have been better served he referred to later figures; for demobilisation the Army of Occupation between them were to a further rise in 1946. Latest figures, however, a decline, particularly in syphilis.

or many years (both by private instruction at clinics from the public platform) I have advocated personal fection as one of the means whereby the incidence D. could be reduced; and other medical men have the same. During the late war I had the privilege elping some of our Allies to improve methods of ical disinfection. The National Society for the ention of Venereal Diseases might, therefore, I think, me as an ally; but I part company with them they pretend that the spread of knowledge on fection will bring about the elimination of V.D.

rd Horder talks of "a great campaign to set the le free from V.D.," saying that "the scope and itude of this great attack depends upon the support eceive from the profession and from the general ic." And what is his great campaign? To tell the l the virtues of urination after coitus, soap and water, sium permanganate solution, and calomel cream! peaks of a scientific fact known for 40 years, but we iving now in a penicillin era in which it is claimed a single injection, taking less than one minute to inister, can cure 90% of cases of gonorrhœa. Gonorrhœa has largely been robbed of its terrors for man, woman, and infant.

A quarter of a century ago, the Trevethin Committee, gave its blessing to "properly and promptly applied disinfection," but no-one who understands the significance of the operative words "properly and promptly" will suggest that the average man, however well instructed, will, after venery, efficiently disinfect himself; and Lord Horder knows that the relatively successful disinfection in the Fighting Services during the war was carried out largely under skilled supervision, which he does not propose for the civil community.

The Trevethin Committee recommended also the trial for a period in a limited area, of powers to compel defaulters and suspected sources of infection to undergo treatment. Far more is to be expected from tracing and treating contacts than from teaching disinfection, although both are required. By all means tell the public about calomel and Condy's fluid, but tell them also that in England today there is no law to assist the V.D. officer and the medical officer of health to bring under treatment men and women known to be spreading gonorrhœa and syphilis, the contacts of fresh infectious cases, the man who has infected his wife, the wife who has infected her husband, the parents of infected children, or the brothers and sisters of young congenital syphilitics.

Brentwood. ROBERT FORGAN.

PAIN

SIR,—Dr. Keele's (July 3) method of recording pain is certainly appropriate for testing the efficiency of analgesics. But he omits consideration of sensitivity. If in one individual sensitivity to pain were always the same, we might ignore it altogether; we could compare the effects of, say, morphine and distilled water on this particular individual, as Dr. Keele has done. But if we assume that sensitivity even in the course of the same illness is different at different times; if we assume, for instance, that sensitivity is greater during the first minutes or hour after a period of freedom from pain, or that sensitivity to pain wears off the longer it lasts (and these are quite feasible assumptions)—then the conclusions about the effect of an analgesic appear in a very different light.

For example in chart 5, distilled water was ineffective when the pain had lasted only 2 hours, but pethidine was effective when it had lasted 4 hours. May not this difference be explained, partly at least, by the time factor and a reduction in sensitivity due to this lapse of time? In chart 6, pethidine was ineffective when the pain had lasted 1 hour, but distilled water was effective when it had lasted 5 hours. Does this observation prove, as Dr. Keele thinks, that the pain in this case was psychogenic, or was it partly due to the fact that after 5 hours the pain was felt less keenly and was therefore more responsive to medication?

I think that the factor of sensitivity cannot be left out of consideration; but this recording of pain may help in determining how sensitivity is correlated to the time factor. Perhaps a record of untreated pain would be useful, though it might be difficult to achieve this humanely.

Alverstoke. W. J. PINOFF.

ABNORMAL PERIODS OF GESTATION

SIR,—In my early years as a surgeon I often had to deal with obstetric abnormalities, and I still have notes of some unusual cases. In the light of last week's article, the following case-report may interest some of our legal friends.

In May, 1929, a farmer's wife, aged 37, pregnant for the second time, was sent into hospital, and gave a history that her first child was born 9 years previously, after an 8 months' pregnancy. Since then her menstrual periods had been somewhat irregular, the intervals varying from 3 to 6 weeks. Her last period began on June 10, 1928. She made a note in her diary of coitus on June 30. Medical induction of labour was attempted on May 13. The child, weighing 8 lb., was born on May 18, after a gestation period of 342 days.

This is the story, for what it is worth. I had no reason to doubt the accuracy of the patient's statements.

Northampton. C. C. HOLMAN.

Public Health

HEALTH AND DISEASE IN 1946

MINISTRY'S REPORT

THE year 1946 was one of transition from the activities of war to those of peace. This is reflected very clearly in the report for that year of the Ministry of Health's chief medical officer,[1] Sir Wilson Jameson. He alludes, for example, to the general downscaling of the Emergency Medical Service's work; and to the return of Servicemen from overseas, which accounted for a rise in the birth-rate (though the peak was not to be reached until 1947) and also for a rise in the number of reported new cases of syphilis. For the Ministry this year of redistribution had its special problems, one of which proved to be the risk of smallpox dissemination by Servicemen returning by air from the Far East. In general, however, this, like its war-time forerunners, was a year of good health.

STATISTICS

As a result of the rapid demobilisation after mid-1945 the mean population of civilians in England and Wales increased to 40,745,000, compared with 38,157,000 in 1945. The birth-rate, which had declined in 1945, rose to 19·1, while the civilian death-rate fell to 12·0—a level around which the crude death-rate fluctuated between the two wars. The causes which continued to account for increasing numbers of deaths were cerebral hæmorrhage, cardiovascular disease, and cancer; these groups, together with senility, accounted for 63% of non-violent deaths. Infant mortality fell sharply, after a slight setback in 1945, bringing the rate to a new low level of 42·9; and deaths in each year of age up to 5 also declined to new low records.

INFECTIOUS DISEASES

Smallpox.—There were 56 cases, of which 14 proved *fatal. All the cases, which made the largest total* since 1934, arose during the first six months of the year and in circumstances suggesting that the infection originated in India. It was repeatedly observed that when smallpox of the major Asiatic variety attacked vaccinated patients, whose immunity had presumably begun to wane, it assumed a clinically mild form, with a modified and sparse eruption. Such cases sometimes went completely unrecognised, but they were nevertheless highly infectious. The report suggests that successful control of imported smallpox depends on: (1) prompt recognition and isolation, aided by laboratories able to carry out serological tests and the culture of variola virus; and (2) identification, inspection, and prompt vaccination of all probable contacts, using at least two insertions, followed by daily surveillance for at least 16 days from the last exposure. Each of the 3 cases of postvaccinal encephalitis was in a patient who underwent primary vaccination at school age or later.

Diphtheria.—The corrected number of notified cases was 11,986, and of deaths 472. For 1945 the comparable figures were 18,596 and 722; and, for 1944, 23,199 and 934. It is noteworthy that of the "protected" children with a known history who died of diphtheria in 1945, none had received a boosting dose of prophylactic; the period between the date of protection and of death varied from a few weeks to ten years, the majority having been protected more than four years previously. The report records, as an object-lesson, an outbreak traced to two domestic servants, of whom both had septic skin lesions and one otorrhœa; *Corynebacterium diphtheriæ* was isolated from the skin lesions ear discharge but not from the nasopharynx.

Scarlet fever.—The regression in numbers cont there were 56,730 cases and 43 deaths. The report

> "Where possible, *patients suffering from* streptococcal throats, whether of scarlet fever type or not, are best at home, rather than in a multiple bed ward of an hospital with its multiplicity of types, each capable of cross infection. In an outbreak of so called scarl it is essential to deal with all cases of streptococcal inf

Measles.—This was in the minor phase of its b epidemicity. There were 160,402 cases and 204 d Of recent years the virulence of the virus has dimini the true hæmorrhagic form has disappeared, "and an ill-omened complication as cancrum oris is a of the past." Since most deaths take place in the you age-groups, the best hope of reducing mortality h postponing the age of attack.

Rubella.—Accounts of congenital defects in chil born of mothers who had rubella in pregnancy prom the Ministry to initiate an investigation in conjunct *with some of the larger welfare authorities.* The r gestion that rubella should become notifiable is reject

Common cold.—By the end of the year the established at Salisbury by the Ministry and the Med Research Council had established that filtered mater stored at −70°C for $4^1/_2$ months retains its cold-induc properties, which are, however, lost after 3 days' stora at 4°C.

Cerebrospinal fever.—Since the eightfold rise notifications between 1939 (1500 cases) and 1940 (12,77 numbers have declined, but the 1946 total (2673) is above the level of 1141 cases per year between 1936 1938. Fortunately the case-mortality, which was in 1930, has fallen and in 1946 was 25·3%. Th tinued high prevalence is, however, disturbing: prevention the first aim should be to lower the rate.

> "Paramount among the general measures is the av of overcrowding. . . . chemoprophylaxis now offers specific protection. The general administration of doses of sulphadiazine, one gram a day for three d reported to have brought down high carrier rates of 50 per cent. in military units to a very low level and to terminated outbreaks of meningitis immediately."

Enteric fever.—The Public Health Laboratory S has undertaken to place its resources at the disp medical officers of health; and it should be possib compile a national register of carriers of partic Vi-phage types of typhoid and paratyphoid h leading to the avoidance by these carriers of f handling and other potentially dangerous occupati "Had it been possible to apply such control years ago the Aberystwyth outbreak might have averted."[2]

Jaundice.—In the area where jaundice was not the rate per 1000 of the population was 0·7, the h figures appearing in April and May. Through country the aggregate of deaths from acute atrophy, hepatitis, jaundice, and catarrhal j exceeds 500 a year. "If half of these deaths be infection . . . communicable jaundice has of lat killing more than scarlet fever, the dysenteri enteric fever."

Malaria.—The report records the case of a woman to whom the infection was conveyed by transfusion shortly before delivery. Subsequentl developed malaria, and quartan parasites were fou her blood; but the child escaped infection. The d was found to be a carrier of quartan parasites.

---

[1] Report of the Ministry of Health for the Year ended March 31, 1947, including the Report of the Chief Medical Officer on the State of the Public Health for the Year ended Dec. 31, 1946. H.M. Stationery Office. Pp. 204. 3s. 6d.

[2] See Bevan, G., Sudds, M. V. N., Evans, R., Parker, M. T., I., Sladden, A. F. S. *Lancet*, 1947, i, 545.

ereal disease.—The number of new cases of syphilis ling treatment centres rose from 5214 men and women in 1945 to 10,705 men and 6970 women in The increase was caused largely through bilisation; but there was also evidence that ion was imported from the European mainland. ver, infantile congenital infections rose only slightly n 326 to 363. That the promiscuous woman is nain reservoir of infection not only for syphilis lso for gonorrhœa is indicated by the clinic figures is disease. In 1945, 21,280 men and 11,603 women led for treatment. In 1946 the male cases rose ,912, whereas the female cases fell to 10,431. As nicillin:

p to the present, there is no certain evidence that nt strains of gonococci are in circulation, and the great ity of relapses are cured by re-treatment with penicillin." treatment of syphilis, "the discovery that commercial llin has been liable to contain an undefined proportion e less efficacious penicillin IV(K) has justified the ry's decision not yet to recommend its exclusive use."

berculosis.—In the war years deaths averaged 0 and the rate 619 per million. In 1946 a new ecord for both respiratory and other forms was lished, total deaths numbering 22,847 and the rate 533.

here is, however, no room for complacency in face of a e which still causes nearly one-third of all deaths at 15 to 39. Mortality from respiratory tuberculosis in ountry is highest among young women and men of e age. The rate for men over 65 has shown a subal increase since the war, due, it may be presumed, to visations of lesions which might have remained dormant or the strains and stresses of war."

spite an increase, in 1945 and 1946, of 2440 in the ber of beds provided, the battle of the waiting-list being lost. The main (88%) reason for non-availty of empty beds was shortage of nursing and estic staffs.

to the end of 1946, 1,369,014 people had been examined nass radiography. Of those examined 95% were found ave no abnormal chest condition. Previously unsusd active tuberculosis was found in 4 per 1000; and ive tuberculosis, excluding calcified primary lesions, %. Of other conditions, acquired cardiovascular lesions detected in the same proportion as was active tuberis: bronchiectasis was found in 1 per 1000 of males and er 1000 of females; intrathoracic malignant disease was ted in altogether some 170 cases; and retrosternal oid in some 80 cases. Of those recalled for further ination over 97% responded.

MATERNAL DEATHS

e Ministry received confidential reports on 769 rnal deaths; and in 284 of these, investigators found ssessable avoidable factor.

Investigators' conclusions	*No. of maternal deaths*
ack or inadequacy of antenatal care	86
ack of coöperation by patient or her friends ...	70
ack or inadequacy of obstetric facilities	59
ack or inadequacy of hospital or specialist treatment	46
oor general health or malnutrition	18
isk of pregnancy should not have been undertaken	3
nsatisfactory home conditions	2
	284

FOOD AND NUTRITION

e introduction of bread rationing in the second half e year meant the abolition of the main reserve from h requirements above the average could be satisfied. extraction-rate of flour was again raised to 85%.

e body-weight surveys of the Ministry of Food revealed line of about ¾ lb. in the average weights of adults aged 34 years since the middle of 1945, compared with a fairly steady increase, of 2–4 lb., from 1943 to 1945. On the other hand, data for heights and weights of school-children (available only up to mid-1946) show that improvements in height and weight of the later war years were on the whole being well maintained.

HOSPITALS

At many hospitals priority in building was given to the provision of improved amenities for staff. In one representative region nearly a third of all the projects approved, and about half of the estimated expenditure, was in respect of nurses' homes. The adaptation of emergency hospital huts to a variety of general and special uses was put in hand. High priority was given to maternity buildings.

MONTHLY SURVEY OF SICKNESS

The chief features brought to light by the Social Survey's monthly review from 1944 onwards were a pronounced fall in minor complaints during the spring and summer of 1945 (perhaps connected with the ending of the war), high levels for such ailments at the end of 1946, and an apparent increase in more serious illness amongst elderly women throughout 1946.

Among those under 65, varicose veins accounted for about 1½ days lost per 100 people each month, and cardiovascular disease for 2½ days lost. From all kinds of illness and injury the average of days lost each month per 100 people was 114 for men and 86 for women.

In his introduction to the report Sir Wilson Jameson acknowledges the medical profession's work in these words: "Posterity, remembering the straitened means at their command, will, I think, wonder at their achievement in this troubled post-war year."

Parliament

"Medical Black Market"

IN the House of Commons on July 20 Miss A. M. BACON spoke of a black market being created by a minority of doctors who were refusing to accept on their lists patients whom they believed capable of paying high fees or those who needed extra attention, such as old people, children, and the chronic sick. Another type of doctor "more subtle, but no less sinister," agreed to accept patients but told them that they would not get the same attention, or the same drugs, as when they paid fees. "Doctors are losing many friends," said Miss Bacon. "Many people who opposed the health scheme would now be in favour of a full-salaried service. These practices are bringing the scheme into ridicule and contempt. They are a travesty of the humane spirit in which the Act was conceived."

Mr. ANEURIN BEVAN, Minister of Health, said that the practices described were carried on by a very small proportion of doctors: the vast majority of the profession regarded such conduct as quite intolerable. For a practitioner to accept some members of a family as his patients, while refusing one or more of the others cut right across the conception of a family doctor. The scales of remuneration for the profession were drawn up on the assumption that the whole population might be in the scheme, and the standard of remuneration for practitioners was higher than that of 99% of other people. Where doctors were saying to potential patients that they could afford to pay, they were in most cases saying it to people whose income was lower than their own: and there was no justification on financial grounds for this discrimination. Mr. Bevan went on to suggest that an area where a doctor or doctors accepted patients only in return for fees might be regarded as under-doctored. This would be a matter for the Medical Practices Committee. The practitioner was expected to provide adequate facilities for his patients, and it would not be considered proper for a practitioner to provide superior facilities for his private patients as against his public patients. He was asking local executive councils to look into this matter immediately.

Food-supplies and Nutrition

In the House of Commons on July 12 Mr. J. S. C. **Reid** said that a year ago some people still argued that ours was a well-fed nation and that there was no need to worry about the future of our food-supplies. But the Economic Survey for 1948 set out the precise respects in which there had been a fall in the consumption of a number of commodities, and stated that it would be wholly misleading to infer that the real standard of life had remained, and would remain the same. The figures showed that the food available during the year had, on the average, diminished by 200 calories per head per day. Mr. Reid did not attach primary importance to that figure: it would be of primary importance only if there were equality of sharing of the food available. This, of course, was not the case: a great many quite properly got more than the average through canteens, school meals, and extra rations, and a great many people therefore got less. It was time that the Minister re-examined the method of his department in deciding who was to get extra allocations of food. Applications were never refused because the applicant did not need the extra food, but always for some administrative reason. Mr. Reid appealed for an end of the "sorry business" of bread rationing, and for a lowering of the extraction-rate for flour.

Mr. **John Strachey**, Minister of Food, hoped and trusted that the time would not be long delayed when bread rationing could be ended. Obviously, too, the Government would like to lower the extraction-rate further, and he agreed that if it could not be lowered by 5% it would be well worth the while to lower it by $2^{1}/_{2}$%. If he were in a position to do that he would certainly do so, but he would give the ending of bread rationing priority.

It was perfectly true, he said, that last autumn the nutritional prospect for the first six months of 1948 was a dark one indeed, and his nutritional and scientific advisers had looked forward to that period with the greatest apprehensions. But as a matter of fact the calorie level remained almost exactly 2800, and did not fall below 2700 as they had feared. This was done by switching from dollar sources of foodstuffs to sterling and other currency sources. Even 2800 calories, however, was a low figure, and only just sufficient. Therefore it was essential to have the fairest possible distribution. If food subsidies were abolished, fair sharing would be impossible: the steep rise in prices which would immediately take place would sharply cut down working-class consumption. If people asked what value they were getting for these subsidies—which were now running at something like £470 million a year—he asked them to look first of all at our children. After examining children in our schools Prof. Henri Bonnet, of the French Academy of Medicine, said: "In 10 years, England will have a generation of young men and women superior, physically and mentally, to those of any other European country. I am convinced that the excellent physical condition of these children is due to their feeding. Their diet is perfectly balanced, and the system of milk in schools, school feeding and extra vitamin nourishment provided by clinics has had obvious results." The percentage of school-children receiving meals in schools was now 52, compared with 4 before the war.

Dealing with the world food situation, Mr. Strachey said he did not think there was any necessary conflict between his views and those of Sir John Boyd Orr. Sir John was assuming that the vast populations of China, India, and the like must be brought up for the first time in human history to a satisfactory level of nutrition. That was something which everyone would pray for and wish to advance, but it was something altogether outside the scope of anyone speaking for the British Government. It could only be handled by these people themselves. He (Mr. Strachey) spoke only of the world food situation at the current level of effective demand. If that level was raised, as it easily could be if everyone in China and India secured adequate food, then the world would be desperately short of food for a very long time. But at the current level of effective demand it appeared to him that in the basic foodstuffs of rice and cereals we ought to see an improvement in availability the coming year. The chief lesson for us of th critical nine months we had been through betwe convertibility crisis of the European Recovery gramme was that the great food-producing co had as much need of us as we had of them. The he believed that, as long as we had an industrio ingenious population producing manufactures i country, we could be assured of feeding ourselves.

Dr. **Edith Summerskill**, parliamentary s to the Ministry of Food, replying to the debate, tribute to the work of Sir John Boyd Orr, M.D., F. director of the Food and Agriculture Organ At two conferences of the F.A.O. she had delegates from every part of the world listen to Sir with respect, admiration, and affection. He wa only a great scientist and a great humanitarian but been one of our finest ambassadors. If it was true posterity remembered those who benefited post. Sir John Boyd Orr could never be forgotten.

The population of the world, said Dr. Summ was increasing by 25 million a year. The great Dom of Pakistan and India intended to eliminate illit and when that was done it would inevitably mean peoples would demand a standard of living compa to those enjoyed in the west. Not only would t population increase, but their expectation of life wo also increase. Malthusian doctrine, which was discred in the 19th century, would perhaps be vindicated the end of the 20th.

Mr. **Emrys Hughes** suggested that Sir John Boyd O should be sent on a special mission to Moscow to whether Russia could be persuaded to come back t the F.A.O. and coöperate in a world food plan.

Housing Progress

Replying on July 14 to a debate on housing pol Mr. **John Edwards**, parliamentary secretary to t Ministry of Health, said that in May, 1947, 21 out of a total labour force of 480,000 in Engla Wales were employed on housing work. The co figure for May, 1948, was 220,000 out of a tot of 481,000. In the summer of last year it was that the desired spread of housing had been o and that in order to secure the completion of h already in the programme it ought not to be overl with additional contracts. The decision to restr retard the number of new contracts was not a de to cut down the housing programme, but simp necessary step to secure the more rapid completio houses for which contracts had already been let. result was a much better balanced programme. number of houses completed in relation to those construction had increased from 1 to 18 in May, to 1 to 10 in May, 1948. The Government's present was to keep the volume of building constructi England and Wales at approximately 180,00 houses.

Speaking later, Mr. **Bevan**, Minister of He announced that permanent new houses were completed at the rate of 20,000 a month. Th were good reasons, he said, why waiting-lists for h were no longer an expression of housing needs the end of the year he was going to ask local auth to "vet" them.

A motion by Mr. **Walter Elliot** to reduce Ministry of Health vote was negatived by 303 votes

Proprietary Medicines

On July 12 Mr. A. M. **Skeffington** said that it a little ludicrous and illogical that, when the was spending possibly £100,000,000 a year on services, the advertising of proprietary medicines encourage self-medication, with its obvious danger.

Sir **Ian Fraser** pointed out that proprietary med were subject to $33^{1}/_{3}$% purchase-tax, which natu raised their cost. Not everyone could see a d there was a shortage of doctors, and many of preparations were identical with those recomm by the medical profession.

Mr. **Edwards**, parliamentary secretary to the Mi of Health, said that voluntary efforts had been ma some of those most directly concerned to keep ext gant advertising of proprietary medicines in y that, under the National Health Service, everyone ld have the medicines prescribed by their doctor necessary, there was less reason for people to buy licines for which misleading claims were made.

Supply of Artificial Limbs

n the House of Lords on July 14, in reply to Lord NCROFT, Lord MORRISON stated that under the ional Health Service an artificial limb, where required, ld be supplied free. Normally the limb would be of same type as the limb now supplied to disabled Servicemen by the Ministry of Pensions through r own contractors. But it would be possible for one to elect to be fitted with another make of limb roved by the Ministry, provided that he accepted onsibility for any increased cost. This option would ly to all patients, including disabled ex-Servicemen.

ord WEBB-JOHNSON, P.R.C.S. (who had that day been oduced and taken his seat) expressed satisfaction the Government's answer. This question, he said been a source of great anxiety to practising surgeons, only on account of patients at the moment, but also ause of the possible effect in preventing future elopment.

The Death Penalty

he House of Commons on July 15 considered the minal Justice Bill.

ir HARTLEY SHAWCROSS, Attorney-General, moved t the House should disagree with the Lords' amendnt to delete clause 1 (suspension of the death penalty murder). He urged the merits of the Government's posal to recognise two categories of murder—the ital and non-capital. He thought that juries would e no difficulty in deciding whether a murder came one of the five classes for which capital punishment reserved: (1) those committed in connexion with bery, burglary, or house breaking (gangster offences); unding by three or more persons acting together; ences committed with explosives or destructive subnces; rape, indecent assault, and sodomy; (2) murder a police officer, or a civilian who was assisting a police icer in the execution of the law; (3) poisoning when poison had been systematically administered; the murder of a prison officer; and (5) second murders.

Mr. WINSTON CHURCHILL said that the new clause l been put together with the object, not of making etter and more humane system of criminal justice, of getting around an awkward Cabinet or Parliantary difficulty. The Government's clause would aken the jury's sense of responsibility and introduce tinctions that would puzzle and baffle them, while its onsistencies and absurdities would tend to bring the into disrepute. The most frequent types of murder, h as wounding, stabbing, and drowning, and the st wicked murders, would not carry the death penalty.

Sir JOHN ANDERSON thought the new clause unsatistory because it sought to substitute a rigid and borate statutory code for the existing flexible, welld system. He thought that the words "express lice" would give rise to serious difficulty. The only sible and sensible course for those who believed that capital sentence was an unavoidable evil, and would to see it got rid of to the fullest possible extent l as speedily as possible, was to proceed by the rcise of the Royal prerogative. Mr. CHUTER EDE, me Secretary, on the other hand, believed that the ler use of the Royal prerogative would involve the me Secretary in considerable difficulties. The Governnt had put before the House a method by which ady amelioration of the law could be carried forward a way that would not violently offend public opinion.

After a series of divisions, the Government's commise clause was carried by 307 votes to 209.

QUESTION TIME

etropolitan Police Officers and the Health Service

ir E. GRAHAM-LITTLE asked the Home Secretary what lical arrangements had been provided for the Metropolitan ice under the new Health Insurance Act and, in particular, ether they were insurable under the Act and would have free choice of doctors or be attended by their divisional surgeons as up to the present.—Mr. C. EDE replied: Members of the *Metropolitan Police Force, like other police officers, are* now compulsorily insured under the National Insurance Act and the Industrial Injuries Act. In view of the establishment of the National Health Service, Police Regulation 88, under which police authorities were required to provide free medical attention for police officers, has been revoked, and police officers, like other citizens, have free choice of doctor. I understand that the majority of the divisional surgeons in the Metropolitan Police District have joined the National Health Service. Accordingly police officers who wish to continue to receive attention from their doctor will be able to do so.

Obituary

GORDON WILKINSON GOODHART

M.A., M.D. Camb., F.R.C.P.

Dr. Goodhart died at his home in London on July 16. He retired last year from his post as pathologist to the London County Council group laboratory at St. Mary Abbots Hospital, and would have been 66 on July 24 of this year. The younger son of Sir James Goodhart, of Guy's Hospital, and heir presumptive to the baronetcy, he was educated at Westminster School, Trinity College, Cambridge, and Guy's, where he became successively house-physician, Gull research student, demonstrator of pathology, and senior assistant bacteriologist. Later, at Freiburg, he worked for a time with Aschoff, before becoming clinical pathologist at University College Hospital. During the 1914–18 war he served in France in the R.A.M.C., and was pathologist to the 2nd London General Hospital. Of his next few years, W. G. B. writes:

I first met Goodhart in October, 1923, when he was clinical pathologist to University College Hospital. His laboratories, at the top of that building were extremely well run and he was freely consulted by all the clinicians there. It was a distinguished staff—Sir John Rose Bradford, Martin, Batty Shaw, and Poynton, with Bolton, Elliott, and Sir Thomas Lewis as junior physicians. A visitor to Goodhart's laboratories would immediately be struck by the general atmosphere of friendliness, and at the same time by the high standard of accuracy and the spirit of investigation which spread through the laboratory from Goodhart to all his assistants and technicians.

At this time he was actively engaged in research with Bolton on gastric secretion and the neutralisation of stomach contents, and with Price-Jones in investigations of the blood. A. E. Boycott, who was professor of pathology, had worked at Guy's and had brought Price-Jones with him; so Boycott, Price-Jones, and Goodhart were all well known to each other before their collaboration at University College Hospital.

Goodhart was interested in all aspects of pathology, and his contributions to them were mostly in the teaching of his students and the training of his assistants, most of whom have since achieved distinction. His work with Bolton was outstanding, and as a hæmatologist he was greatly distinguished. As a man he was extremely friendly. He was a great story-teller and could give long and interesting accounts of the many people with whom he had come into contact since his boyhood. Although these tales might take long in the telling, they never bored; they were always suffused with kindness, and were generally highly entertaining. He was extremely happy in his family life and enjoyed to the full his very large circle of friends, by whom he will be greatly missed.

In 1931 Goodhart left U.C.H. and played a great part in the establishment of the highly successful pathological services run for and by the London County Council. He worked first at the Archway group laboratory, and later, when a new laboratory was opened at St. Mary Abbots, he moved there. He was, at various times, president of the section of pathology of the Royal Society of Medicine, of the Medical Society of London, and of the Association of Clinical Pathologists.

In 1914 he married Alice Stransham La Touche and they had two daughters and a son.

WILLIAM AUSTIN ROBB

M.D. LOND., F.R.C.P.

Dr. W. A. Robb, pathologist to the Royal Devon and Exeter Hospital, died at his home on July 12, at the age of 55. Born at Burnt Fen, near Ely, he came of Suffolk yeoman stock and in youth hoped to become a veterinary surgeon. His passion for the country and for animals never left him; but by pure chance he took up pharmacy, and in this he showed such aptitude that he had taken the major pharmaceutical diploma by the age of 21. On the outbreak of the 1914–18 war he enlisted at once in the R.A.M.C., and in France he was sergeant-dispenser in the 36th Field Ambulance, in which his name became a byword for efficiency. The *Pharmaceutical Journal* of July 26, 1919, contained the following comment which bears this out: "I would like to compliment the man in charge of the dispensary of the 36th F.A. Had you seen his pharmacy under indescribable conditions you would have wondered how he did it. His officers used to marvel at him and were never tired of singing his praises."

In the German break-through of 1918 Robb was seriously wounded and taken prisoner while superintending the evacuation of casualties. On recovering in a German hospital, his work and care of patients of all kinds (German and otherwise) became so valuable that his captors pressed him to stay instead of going to a prisoner-of-war camp. Robb refused, in order to throw in his lot with his fellows, to whose service he devoted himself wholeheartedly. His war experience caused him to take up medicine, and in 1919, directly on demobilisation, he went to Barts from which he qualified in 1924, taking both the M.R.C.P. and M.D. in 1926. He became devoted to Langdon-Brown, to whom he was house-physician and chief assistant—a post he held until he could resist no longer the call of the country. He thus was led to Exeter in 1931, where he remained as pathologist until his premature death.

With his pharmaceutical background, it was natural that his experience was used, first as a teacher of practical pharmacology at Barts and later as a member of the revision committee of the *British Pharmacopœial Codex*. During the late war he added to his many appointments that of regional resuscitation officer in the E.M.S.

Such are the bare facts in the life of a character of great friendliness who will be sadly missed in the South-West. Austin Robb was of an all too rare type; thoroughly consistent to the root traditions in which he was bred. He was passionately fond of the country, and there were few parts of Devon of which he did not have an intimate knowledge gained from prodigious journeys on foot; he was able to surprise many medical colleagues by his knowledge of where their patients lived. His fondness for animals even led him to allow his chickens to wander through the flower garden "because it pleased them"! He was a loyal son of Barts and his home was a constant place of pilgrimage for his older and contemporary colleagues. He was a man of deep religious feelings without making it obvious; as a student these were coloured by his experience of life of a grimmer sort, and were more real than the adolescent gropings of the younger men who were his fellows. In later life he was a constant supporter of his church, and at the same time enjoyed life to the full. He lived well, he read prodigiously, he was a connoisseur of art, and he had a wonderful sense of humour.

In medicine his greatest achievement was of the unspectacular type, as a clinical pathologist. He was no pure laboratory man, though he established a first-rate pathological service. Technically he strove hard for perfection; he would not compromise with inefficiency or humbug. He made pathology what it should be—the basis of good clinical practice. In his office medical men came to discuss their pathological problems and went away enriched not only with the light of technical investigation but with a wealth of clinical sense; indeed with the illumination of a great physician.

As one who knew him as a friend and colleague, I would like to add one further note from the patient's viewpoint. Illness to Austin Robb was a personal problem not confined to physical signs and laboratory tests. As a patient one felt the whole impa his character: it was a chastening and invigo experience.

He leaves a wife and two children.

N. C

THE LATE CAPTAIN WATSON

A tribute to Captain Edward Clifford W R.N. retd., who died last August, reaches us J. B. G. S. who served with him in the late war. taking up medicine Watson had already had a tinguished career in the Royal Navy: in the first war he was an Admiralty consultant in radio prob After twenty years' service he retired with the rank commander, and he was later promoted captain on retired list. In 1930 he qualified as M.R.C.S. St. Mary's Hospital, London, where he held the post resident obstetrical officer before going into practice Twickenham. On the outbreak of the late war returned to the sea, and he served afloat throughout war, mostly in command of minelayers. "All so long out of touch with Naval affairs, he had for none of his seamanship and navigation; and he awarded the D.S.O. for services in minelaying while command of H.M.S. *Twistbank*. As medical officer *Twistbank* for two years, I had reason to be grateful his helpfulness. His last days were spent as heal adviser to the government of Trinidad."

Medicine and the Law

Similar Containers Again

AT a Birmingham inquest earlier this month t house-surgeon of a maternity hospital admitted th the death of a month-old infant was due to his mista in taking fluid from the wrong container for washing vein after a transfusion. He had used meth other instead of a saline solution. The deputy c recalled that a similar fatal mistake had been ma the same city at another hospital two years ago. press had reported this previous incident in 1946 local hospital managers must have discussed it; the lesson of the tragic error had not been applied. hoped that hospitals would take all possible steps prevent a further repetition. In particular he mentio the recommendation put forward by one witness in that containers of different colour should be used. T suggestion, he thought, would not only avert th tragedies but would also ease the surgeon's task giving him less to concentrate upon in the course of actual operation.

Appointments

BODOANO, AGNES, M.B. Manc.: pathologist, Keighley and Di Victoria Hospital, Yorks.

DAVIDSON, W., M.B., D.M.R.D.: asst. radiologist, Royal I Infirmary.

JOHNSTON, E. A., M.A., M.B. Aberd., D.P.H.: chief M.O.H., Inve shire.

McWILLIAMS, L. F., M.C., M.B. Belf., D.P.H.: asst. M.O. and Hucknall, Notts.

PHILPS, A. S., F.R.C.S.: surgeon i.c. eye department, St. B mew's Hospital, London.

WALKER, J. V., M.D. Birm., M.R.C.P., D.P.H.: M.O.H., Darli

Hospital for Sick Children, Great Ormond St.:

- COLE, PAULINE, M.B. Lond.: house-surgeon.
- DUDGEON, J. A., M.C., M.A., M.D. Camb.: asst. patholog
- GORDON, W., M.B.: house-surgeon.
- JOLLY, H. R., M.A., M.B. Camb.: house-physician.
- MACLEAN, W. E., M.D. St. And., M.R.C.P., D.C.H.: receivi physician.
- WALTHER, D. P., M.R.C.S., L.D.S. R.C.S.: orthodontic regi
- WESTHEAD, PAMELA, M.B. Brist.: resident anæsthetics re
- WETTENHALL, H. N. B., M.D., M.R.A.C.P., M.R.C.P.: physician.

Royal Isle of Wight County Hospital, Ryde:

- CLAY, R. D., B.SC., M.B. Lond.: morbid histologist.
- HARKNESS, JOHN, B.SC., M.B. Glasg.: biochemist.
- SWINSTEAD, P. D., M.B. Lond.: asst. pathologist.

Colonial Service:

- FARQUHARSON, A. D. J., M.R.C.S.: M.O., Nigeria.
- SWORD, J. M., M.B. Glasg.: M.O., Nyasaland.

Notes and News

WINDOW ON THE WALL

Orsett Hospital, Essex, the wards are gaily and subtly red, while a changing exhibition of lively pictures on the has hitherto gladdened the eye. Such unusual cheers derives from the taste and imagination of Dr. L. the superintendent, who has recently had a fresh idea ntertaining the old people who occupy his beds. The have now been decorated with two series of murals. ed by students of the South-East Essex Technical ge and School of Art, under the supervision of Mr. F. A. or, director of the department of arts of the college. The es were chosen by Dr. Cosin to remind elderly patients eir youth, and have been executed in tempera. One e two series shows active scenes in 19th-century life, ther scenes on the Thames from its source in the Cots- s down to the estuary at Tilbury.

. Adrian Hill, the author of *Art versus Illness*,[1] and pioneer t as a form of occupational therapy, opened an exhibition ese mural decorations at the hospital on July 9. He e of the drab or boring surroundings in which most term patients have to spend their days, and wished more doctors were obliged to try the experience. Most nts long for a window by their bed, though this is not ys possible. But what after all, he asked, is a good re but a window? A double window, he might have said. ing something of the thing seen and more of the artist saw it.

. Cosin has found that not only the patients but the are brightened by pleasant colours and good pictures on valls. Now, when it is specially necessary to make the of old buildings, he advocates the general use of colour: the first hospitals to be reborn in paint should be those he aged and chronic sick, for these patients may see no r surroundings for the rest of their days.

AUSTRALIAN NATIONAL UNIVERSITY

rof. Douglas Copland, D.SC., has been appointed vice- ncellor of the proposed National University of Australia, Canberra. The *Medical Journal of Australia* (July 10) orts Professor Copland as having expressed the hope that arch in medicine and physics would be organised there der the guidance of " Sir Howard Florey, F.R.S., and f. M. L. E. Oliphant, F.R.S.

FOR POSTGRADUATE VISITORS

HE Empire Medical Advisory Bureau established in don by the British Medical Association was opened July 13 by Lord Addison. Besides providing information at postgraduate instruction, the bureau will offer a onal advisory service; an accommodation register is to kept, and private hospitality will be arranged. The ctor is Dr. H. A. Sandiford.

EPSOM COLLEGE

'HIS term 511 boys, about 150 of them day-boys, have nded the college. The previous highest total was 480 1938. In its report, the council of the Royal Medical ndation records a loss of about £7000 in 1947; and next n the fees are to be raised to £215 per annum for a boarder . £90 for a day-boy, with a reduction of £10 for the son of loctor and £5 for the son of a dental surgeon. Fewer n 20 boys have been withdrawn as a result of this increase. report was unanimously approved at the annual meeting July 9 when Lord Leverhulme, who presided, said that view of the agreement, arising from the Fleming report, ake five boys a year from primary schools, it had become essary for the school to be inspected by the Ministry of ucation.

PECKHAM

ueen Mary, with the Prime Minister and other members he Cabinet, was present last week at the premiere in this ntry at the Odeon Theatre, Peckham, of a film, *The Centre*, cribing the work of the Peckham Health Centre. Originally ounced to take 45 minutes, it actually occupied less than f an hour, which gave the impression that it had been , especially as the salient information about the promotion he health of the people was not evident. The film presents good picture of the social life of the centre, which was emphasised by all the performers being drawn from the members.

The point made by Dr. Scott Williamson in his opening remarks, that the object of the work is to find what is right and healthy in life and not what is wrong and diseased, was not embodied in the film. Nor did it really show the contribution of the centre to family life; indeed the quarrel between Jones and his wife rather suggested that joining the health centre might cause domestic disharmony.

The film was made at the request of the Foreign Office and was shown at Lake Success to the World Health Organisation. Before it journeys further afield, Mr. Paul Rotha should introduce more evidence of the work which has been done at the centre and which is the basis of the establishment of the National Health Trust for research.

CARD-INDEX GUIDE TO THERAPY

A CARD-INDEX has one outstanding advantage over a textbook—that it can readily be kept up to date by replacing the cards. This form is therefore particularly suitable for a reference work on modern treatment, which is constantly changing. *The Practitioner's Card-Index Guide to Treatment*, published by Devereaux (Medical) Publications Ltd., of 36, Maiden Lane, W.C.2, contains the essentials of therapeutics arranged alphabetically on cards in a convenient plastic cabinet. The information is revised quarterly and the price of 5 guineas covers the first year's replacement cards.

DOCTORS' DISPENSERS

THE Ministry of Health announces that, under the Control of Engagements Order, doctors' dispensers whose employment has terminated following the introduction of the National Health Service will generally register for employment with the Ministry of Labour and National Service. Some of these dispensers have passed the examination of the Society of Apothecaries for assistants in dispensing; some have been trained in the R.A.M.C. or Royal Navy as sergeant compounder or sick-berth petty officer; and some have had long experience with doctors in retail pharmacy. They may be regarded, says the Ministry, as capable of dispensing medicines in both retail and hospital practice under the supervision of pharmacists; and those needing experienced assistants are advised to notify the local office of the Ministry of Labour.

University of Cambridge

A university health service is being introduced, and health service officers have been appointed. Arrangements are being made for a voluntary medical examination, including radiographic examination of the chest, of new students next term.

University of Manchester

The following have been successful in recent examinations:

D.P.M. (part 2).—C. L. Casimir, N. P. Chamarette, Alexander Clark, N. A. Cohen, Barbara M. Dick, J. H. Kahn, R. W. Lennon, M. M. Macrae, W. V. Wadsworth.

University of Edinburgh

The following degrees and diplomas were conferred on July 16:

M.D.—A. H. Banton,*† Agnes A. Brash,* Edward Christianson, A. S. Crawford, J. C. Gilroy,*† I. G. MacKenzie,† D. J. MacRae, Myre Sim, A. D. C. Young.

Ch.M.—J. C. Goligher.

Ph.D.—(*In the faculty of medicine*): N. K. Chowbury, C. C. James,* G. F. A. Rahim.

M.B., Ch.B.—D. W. Atkinson, Alison M. S. Bell, J. D. Bell, Jean Bowden, G. R. Brackenbridge, N. M. Bremner, A. A. Brown, Patricia M. M. Brown, Constance Bruce, J. G. Bulman, Helen L. Burns, Anne Cairns, W. C. Campbell, A. B. Carmichael, Kathleen M. Carmichael, A. B. Cassie, Maureen D. Connolly, Charlotte W. Cordin, J. K. Davidson, L. A. Davidson, Rosemary H. M. Davie,‡ William Davison, D. A. L. Dick, S. M. Drancz, James Drummond, R. B. Duthie, Bridget A. Evans, Mary C. Ewing, Elizabeth W. Ferguson, Sir James Fraser, D. L. Gardner, W. A. Gentle, A. H. C. WILLIAM AUSTIN ROBB

M.D. LOND., F.R.C.P.

Dr. W. A. Robb, pathologist to the Royal Devon and Exeter Hospital, died at his home on July 12, at the age of 55. Born at Burnt Fen, near Ely, he came of Suffolk yeoman stock and in youth hoped to become a veterinary surgeon. His passion for the country and for animals never left him; but by pure chance he took up pharmacy, and in this he showed such aptitude that he had taken the major pharmaceutical diploma by the age of 21. On the outbreak of the 1914–18 war he enlisted at once in the R.A.M.C., and in France he was sergeant-dispenser in the 36th Field Ambulance, in which his name became a byword for efficiency. The *Pharmaceutical Journal* of July 26, 1919, contained the following comment which bears this out: "I would like to compliment the man in charge of the dispensary of the 36th F.A. Had you seen his pharmacy under indescribable conditions you would have wondered how he did it. His officers used to marvel at him and were never tired of singing his praises."

In the German break-through of 1916 Robb was seriously wounded and taken prisoner while superintending the evacuation of casualties. On recovering in a German hospital, his work and care of patients of all kinds (German and otherwise) became so valuable that his captors pressed him to stay instead of going to a prisoner-of-war camp. Robb refused, in order to throw in his lot with his fellows, to whose service he devoted himself wholeheartedly. His war experience caused him to take up medicine, and in 1919, directly on demobilisation, he went to Barts from which he qualified in 1924, taking both the M.R.C.P. and M.D. in 1926. He became devoted to Langdon-Brown, to whom he was house-physician and chief assistant—a post he held until he could resist no longer the call of the country. He thus was led to Exeter in 1931, where he remained as pathologist until his premature death.

With his pharmaceutical background, it was natural that his experience was used, first as a teacher of practical pharmacology at Barts and later as a member of the revision committee of the *British Pharmacopœial Codex*. During the late war he added to his many appointments that of regional resuscitation officer in the E.M.S.

Such are the bare facts in the life of a character of great friendliness who will be sadly missed in the South-West. Austin Robb was of an all too rare type; thoroughly consistent to the root traditions in which he was bred. He was passionately fond of the country, and there were few parts of Devon of which he did not have an intimate knowledge gained from prodigious journeys on foot; he was able to surprise many medical colleagues by his knowledge of where their patients lived. His fondness for animals even led him to allow his chickens to wander through the flower garden "because it pleased them"! He was a loyal son of Barts and his home was a constant place of pilgrimage for his older and contemporary colleagues. He was a man of deep religious feelings without making it obvious; as a student these were coloured by his experience of life of a grimmer sort, and were more real than the adolescent gropings of the younger men who were his fellows. In later life he was a constant supporter of his church, and at the same time enjoyed life to the full. He lived well, he read prodigiously, he was a connoisseur of art, and he had a wonderful sense of humour.

In medicine his greatest achievement was of the unspectacular type, as a clinical pathologist. He was no pure laboratory man, though he established a first-rate pathological service. Technically he strove hard for perfection; he would not compromise with inefficiency or humbug. He made pathology what it should be—the basis of good clinical practice. In his office medical men came to discuss their pathological problems and went away enriched not only with the light of technical investigation but with a wealth of clinical sense; indeed with the illumination of a great physician.

As one who knew him as a friend and colleague, I would like to add one further note from the patient's viewpoint. Illness to Austin Robb was a personal problem not confined to physical signs and laboratory tests. As a patient one felt the whole impa his character: it was a chastening and invi experience.

He leaves a wife and two children.

THE LATE CAPTAIN WATSON

A tribute to Captain Edward Clifford W R.N. retd., who died last August, reaches us J. B. G. S. who served with him in the late war. taking up medicine Watson had already had tinguished career in the Royal Navy: in the first war he was an Admiralty consultant in radio pro After twenty years' service he retired with the r commander, and he was later promoted captain o retired list. In 1930 he qualified as M.R.C.S. St. Mary's Hospital, London, where he held the pos resident obstetrical officer before going into practi Twickenham. On the outbreak of the late wa returned to the sea, and he served afloat throughout war, mostly in command of minelayers. "Alth so long out of touch with Naval affairs, he had forgot none of his seamanship and navigation; and he awarded the D.S.O. for services in minelaying while command of H.M.S. *Twistbank*. As medical office *Twistbank* for two years, I had reason to be grateful his helpfulness. He was a man of strong persona good judgment, and considerable charm; his w knowledge of general affairs was supported by de reading, and when we were in harbour he taught him foreign languages. His last days were spent as heal adviser to the government of Trinidad."

Similar Containers Again

At a Birmingham inquest earlier this month t house-surgeon of a maternity hospital admitted th the death of a month-old infant was due to his mis in taking fluid from the wrong container for washing vein after a transfusion. He had used meth other instead of a saline solution. The deputy c recalled that a similar fatal mistake had been ma the same city at another hospital two years ago. press had reported this previous incident in 194 local hospital managers must have discussed it; the lesson of the tragic error had not been applied hoped that hospitals would take all possible ste prevent a further repetition. In particular he menti the recommendation put forward by one witness in that containers of different colour should be used. T suggestion, he thought, would not only avert t tragedies but would also ease the surgeon's task giving him less to concentrate upon in the course of t actual operation.

Appointments

BODDANO, AGNES, M.B. Manc.: pathologist, Keighley and Di Victoria Hospital, Yorks.
DAVIDSON, W., M.B., D.M.R.D.: asst. radiologist, Royal I Infirmary.
JOHNSTON, E. A., M.A., M.B. Aberd., D.P.H.: chief M.O.H., Inv shire.
McWILLIAMS, L. F., M.C., M.B. Belf., D.P.H.: asst. M.O. and Hucknall, Notts.
PHILPS, A. S., F.R.C.S.: surgeon i.c. eye department, St. B mew's Hospital, London.
WALKER, J. V., M.D. Birm., M.R.C.P., D.P.H.: M.O.H., Darli

Hospital for Sick Children, Great Ormond St.:

- COLE, PAULINE, M.B. Lond.: house-surgeon.
- DUDGEON, J. A., M.C., M.A., M.D. Camb.: asst. pathologist
- GORDON, W., M.B.: house-surgeon.
- JOLLY, H. R., M.A., M.B. Camb.: house-physician.
- MACLEAN, W. E., M.D. St. And., M.R.C.P., D.C.H.: reside physician.
- WALTHER, D. P., M.R.C.S., L.D.S. R.C.S.: orthodontic re
- WESTHEAD, PAMELA, M.B. Brist.: resident anaesthetic
- WETTENHALL, H. N. B., M.D., M.R.A.C.P., M.R.C.P.: physician.

Royal Isle of Wight County Hospital, Ryde:

- CLAY, R. D., B.SC., M.B. Lond.: morbid histologist.
- HARKNESS, JOHN, B.SC., M.B. Glasg.: biochemist.
- SWINSTEAD, P. D., M.B. Lond.: asst. pathologist.

Colonial Service:

- FARQUHARSON, A. D. J., M.R.C.S.: M.O., Nigeria.
- SWORD, J. M., M.B. Glasg.: M.O., Nyasaland.

LATENT TETANY CAUSED BY BAL
2:3 DIMERCAPTOPROPANOL

HOUSE PHYSICIAN,

IN DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL,
LONDON

IE BAL Conference of the Medical Research Council 7) said that BAL is efficacious as an antidote to aicals, forming relatively stable ring compounds . arsenoxides, and thus promoting increased urinary etion of arsenic. It has been used successfully against xication by mercury (Longcope and Luetscher 5) and gold (Ragan and Boots 1947), and is said to roy the complexes formed between these metals and r proteins. In animal experiments it has been found ıbstract nickel, cadmium, chromium, bismuth, and mony, and it may be capable of withdrawing other als, including lead. In a patient with chronic lead oning Telfer (1947) noted a rise of over 100% in ary lead excretion after twelve injections in three s of 1·9 mg. of BAL per kg. of body-weight. These s make it likely that BAL can also withdraw certain ntial kations from the serum and tissues, for it would strange if all body metals were immune from its ience.

he occurrence of cramp-like pains in the limbs, and sms of the fingers, in a patient undergoing treatment h BAL suggested to us that a state of latent tetany ght be present, and the detection of Chvostek's sign both sides confirmed this suspicion. The absence of alosis made it probable that the tetany was of low-cium or low-magnesium type; so we studied the assium, sodium, calcium, magnesium, and inorganic-osphate levels in the serum in this and other patients and unteer students after intramuscular injections of BAL.

TOXICITY OF BAL

imals

Durlacher et al. (1946) state that the convulsions owing BAL are not due to hypoglycæmia. Toxic es produce a metabolic acidosis, shown by a diminished and CO_2 content and increased amounts of serum-tic acid and amino nitrogen. The blood-sugar level s initially but falls to hypoglycæmic levels before ıth. The glycogen content of the liver is reduced, and potassium content of the liver is decreased with rease of the sodium and chloride contents.

Modell, Chenoweth, and Krop (1946) give evidence icating that the high blood lactic-acid level does not ise the symptoms, and that the eye signs and salivation produced by BAL in the circulation and not by that the expired air or in the tears. The signs of salivation l lacrimation also depend on an intact parasympa-tic innervation. A dose of about $^1/_3$ L.D.50 had no ect on the prothrombin-time. Post mortem the only equivocal effects noted were œdema and petechial morrhages in the lungs.

Chenoweth (1946) noted a rise in blood-pressure after all doses of BAL but a fall in systemic and pulmonary erial pressures after larger doses, with a fall in venous ssure except the portal pressure, which was raised. concludes that BAL has a primary constricting ion, but that capillary damage from larger doses ds to increased permeability and signs of peripheral cular failure. A pronounced increase was noted in the e of lymph-flow from the thoracic and cervical ducts. Krop (1946) found a considerable accumulation of tate in the liquid surrounding a stimulated frog's sartorius muscle in the presence of BAL. The initial heat and "twitch tension" were at first increased and later reduced, without significant change in "efficiency."

Man

Sulzberger et al. (1946) studied the toxic effects of BAL injected intramuscularly into 34 healthy young adult males without arsenical or other intoxications. Symptoms were noted 10–30 minutes after the injection of doses equivalent to 3·5–5·5 mg. of BAL per kg. of body-weight daily. No cumulative effects were observed with four doses of about 5 mg. per kg. of body-weight at four-hour intervals, but they were noted when there was only a two-hour interval between the first two injections.

In 11 of the volunteers reducing substances were found in the urine, but other urinary findings were normal. There was no evidence of reduction of the CO_2-combining power of the plasma. Icteric indices were all normal. Respiration-rates increased slightly in 15–20 minutes up to a maximum of 26 per minute. There were significant elevations of the blood-pressure in 30–40 minutes in 14 of 17 volunteers.

In this country the therapeutic dose used has been only about 1·5 mg. per kg. of body-weight (BAL Conference of M.R.C., 1947).

Modell, Gold, and Cattell (1946) studied the effects of BAL on 8 women and 1 man, aged 18–49 years, with secondary or tertiary syphilis. The minimum dose which produced toxic effects was 3–5 mg. per kg. of body-weight. After a single dose of 8 mg. per kg. the symptoms were most severe 5–30 minutes after the injection, increasing gradually in intensity until a level was reached which lasted about 40 minutes, and then subsiding gradually but persisting for between 15 minutes and 2 hours. The blood-pressure and other changes were reversible.

The symptoms of intoxication from BAL as described by these authors, in their exact terms, are compared with the symptoms of latent tetany as described by Strümpell and Seyfarth (1931), with additions from Poulton et al. (1930) as follows:

Toxic symptoms from BAL	*Symptoms of tetany*
Nausea, vomiting	Hypersecretion of gastric juice
Headache	
Burning sensations of the lips, mouth, and throat	Hyperexcitability of the auditory and gustatory nerves
Constricted feelings and pains in the chest	Contractions of the diaphragm
Constricted feelings and pains in the hands, and muscle spasm of the leg	Carpopedal spasm
Conjunctivitis, "tearing," blepharospasm, and burning sensations of the eyes	Recurring conjunctivitis
Rhinorrhœa and burning or tingling of the nose	
Salivation and pains in the jaws	Salivation
Tingling of the hands, pains in the limbs, burning and tingling of the extremities and of the skin, and burning sensation of penis	Paræsthesiæ and pains
Sweating of forehead, hands, &c., and sense of warmth	Hypersecretion of sweat
Moderate to very severe abdominal pain	Painful spasms of diaphragmatic or other muscles of the abdomen, chest, or back
Tremor, general agitation, unrest	Tremors, convulsions in children
Weakness, fatigue	Muscular weakness
Uncontrollable laughter	Occasional hallucinations
Heart-rate moderately accelerated	Pulse increased
Significant rise of systolic and diastolic blood-pressure $^1/_2$ hour after injection, persisting for 15–90 minutes	Increased cardiac activity and vascular spasm

University of Glasgow

Dr. A. Stewart Henderson has been appointed medical officer in charge of the university student health scheme.

A lectureship has been created in tribute to the memory of the late Dr. Noah Morris, professor of materia medica.

Royal College of Surgeons of England

Lister medal.—This medal, which is awarded in recognition of distinguished contributions to surgical science, has been granted this year to Mr. Geoffrey Jefferson, F.R.S., professor of neurosurgery in the University of Manchester, in recognition of his contributions to "knowledge of the functions and structure of the nervous system, made as a philosophical biologist, practising neurosurgery." Professor Jefferson will deliver the Lister memorial lecture in London next June, under the auspices of the college.

This is the ninth occasion of the award, which is made by a committee representative of the Royal Society, the Royal College of Surgeons of England, the Royal College of Surgeons in Ireland, the University of Edinburgh, and the University of Glasgow.

Royal College of Physicians of Edinburgh

A Kirk Duncanson fellowship for medical research has been awarded to Dr. R. M. Marquis, who will investigate congenital malformations of the heart.

Royal College of Physicians of Ireland

On July 9 T. S. W. Buss was admitted a member of the college.

Charing Cross Hospital

Dr. Doyne Bell will give a lecture entitled Points from the Swedish Pædiatric Congress, 1948, in the clinical lecture theatre of this hospital on Wednesday July 28, at 5 P.M.

International Union Against Venereal Diseases

The general assembly of this organisation is to be held this year in Copenhagen from Sept. 6 to 10.

United Cambridge Hospitals

Under an order issued by the Minister of Health, Chesterton Hospital, Cambridge, formerly a poor-law institution, has been transferred from the control of the East Anglian regional hospital board to the board of governors of the teaching hospital.

Medical Society of the L.C.C. Service

At a meeting on July 7 it was decided to change the name of this society to the London County Medical Society. It is intended that the society shall continue to hold monthly meetings, most of which will be clinical; and membership will in future be open to any doctor who wishes to join. Further particulars may be obtained from the secretary, Mr. I. Matheson, F.R.C.S., St. Giles Hospital, S.E.5.

Sir Max Page has been appointed officer of the Legion of Honour of France.

Prof. Alan Moncrieff, director of the Institute of Child Health at the Hospital for Sick Children, Great Ormond Street, has been elected an honorary fellow of the American Academy of Pediatrics.

Diary of the Week

JULY 25 TO 31

Monday, 26th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
5 P.M. Prof. H. A. Harris: Clinical Anatomy of Thorax.
6.15 P.M. Mr. A. Bulloid: Bacteriology of the Mouth.

Tuesday, 27th

ROYAL COLLEGE OF SURGEONS
5 P.M. Prof. D. T. Harris: Autonomic Nervous System.
6.15 P.M. Dr. A. C. Counsell: Etiology of Cysts of the Mouth
EDINBURGH POST-GRADUATE BOARD FOR MEDICINE
3.30 P.M. (Anatomy lecture theatre, University of Edinbur Prof. J. H. Gaddum, F.R.S.: Adrenaline and All Substances.

Wednesday, 28th

ROYAL COLLEGE OF SURGEONS
5 P.M. Mr. M. W. Carr, D.D.S. (New York): Acute Infectio of the Face and Neck of Dental Origin. (Charles Tom lecture.)
INSTITUTE OF LARYNGOLOGY, 330, Gray's Inn Road, W.C.1
4.30 P.M. Mr. V. E. Negus: Organic Nervous Affections of th Larynx.

Thursday, 29th

ROYAL COLLEGE OF SURGEONS
5 P.M. *Prof. Shafik Shalaby (Cairo): Amœbic Liver Absc* (Hunterian lecture.)
5 P.M. Dr. W. A. M. Smart: Circulation.
6.15 P.M. Prof. G. P. Wright: Repair of Connective Tissues.

Friday, 30th

ROYAL COLLEGE OF SURGEONS
5 P.M. Dr. C. Reid: Respiration and Anoxæmia.
6.15 P.M. Prof. R. Hare: Source and Transmission of Wound Infection.
EDINBURGH POST-GRADUATE BOARD FOR MEDICINE
3.30 P.M. Mr. R. C. Brock: Segmental Anatomy of the Lungs.

Births, Marriages, and Deaths

BIRTHS

APPLEBY.—On July 13, at Sheffield, the wife of Captain T Appleby, R.A.M.C.—a son.

COLVER.—On July 15, at Sheffield, the wife of Dr. Thomas Co —a son.

CROCKETT.—On July 9, in London, the wife of Dr. Gerard Cr —a son.

D'ABREU.—On July 10, in Birmingham, the wife of Mr A. L. d'Abreu, O.B.E., F.R.C.S.—a daughter.

FORSTER.—On July 16, at Barnstaple, the wife of Dr. W. M. Fo —a son.

IMRIE.—On July 12, at Guildford, the wife of Dr. D. A. Imrie, M.D.—a daughter.

LE CLERCQ.—On July 13, the wife of Surgeon Lieutenant le Clercq, R.N.—a daughter.

LOVELOCK.—On July 12, in New York, the wife of Dr. J. E. Lovelock—a daughter.

MARQUIS.—On July 16, in Edinburgh, the wife of Dr. R. M. Mar —a daughter.

SMITH.—On July 16, in London, the wife of Dr. W. H. R. Smith—a son.

STANLEY.—On July 15, in London, the wife of Mr. B. E. Craw Stanley, F.R.C.S.—a daughter.

THOMSON.—On July 11, at Falmouth, the wife of Dr. C Thomson, M.C.—a daughter.

TOOHEY—On July 12, in London, the wife of Dr. M. I. Toohey—a daughter.

TYSON.—On July 13, at Singapore, the wife of Dr. W. J. Tyson—a son.

VLASTO.—On July 10, at Weymouth, the wife of Dr. Philip Vla —a son.

WALFORD.—On July 10, the wife of Dr. P. A. Walford—a daught

WHITE.—On July 10, at Berkhamsted, the wife of Dr. Denis White—a son.

MARRIAGES

ENZER—DEACON.—On July 8, in London, John Enzer, to Margaret Deacon.

KELSEY—SHACKLETON.—On July 12, at Askrigg, Francis Kelsey, B.M., to Rachel Fell Shackleton, B.M.

ROSE—RANKIN.—On July 10, at Perth, Ian Falconer Rose, F.R.C.S., to Christian Rankin.

VOWLES—KNOWLES.—On July 17, at Bideford, Keith John Vowles, M.B., to Mary Knowles, M.B.

DEATHS

FRYER.—On July 14, at Pinner, James Fryer, M.B. Glasg.,

GOODHART.—On July 16, in London, Gordon Wilkinson Good M.A., M.D. Camb., F.R.C.P., aged 65.

HICKMAN.—On July 8, at Flax Bourton, Somerset, Henry Ri Belcher Hickman, M.A., B.M. Oxfd, aged 82.

LOUGHNANE.—On July 14, in London, Farquhar McGill Loughnane, F.R.C.S.

LOW.—On July 10, at Tring, Alfred Lees Low, M.B. Edin.

McCAY.—On July 13, at Woking, David McCay, M.D. Belf., lieut.-colonel, I.M.S. retd., aged 75.

O'CONNOR.—On July 12, in Johannesburg, John O'Connor,

SNELLING.—On July 17, at Luton, Trevor Richard Snelling, aged 58.

SYKES.—On July 14, at Bath, John Lewis Sykes, M.R.C.S.

THE BAL Conference of the Medical Research Council 47) said that BAL is efficacious as an antidote to enicals, forming relatively stable ring compounds h arsenoxides, and thus promoting increased urinary retion of arsenic. It has been used successfully against oxication by mercury (Longcope and Luetscher 46) and gold (Ragan and Boots 1947), and is said to stroy the complexes formed between these metals and dy proteins. In animal experiments it has been found abstract nickel, cadmium, chromium, bismuth, and timony, and it may be capable of withdrawing other etals, including lead. In a patient with chronic lead isoning Telfer (1947) noted a rise of over 100% in inary lead excretion after twelve injections in three ys of 1·9 mg. of BAL per kg. of body-weight. These cts make it likely that BAL can also withdraw certain sential kations from the serum and tissues, for it would strange if all body metals were immune from its fluence.

The occurrence of cramp-like pains in the limbs, and asms of the fingers, in a patient undergoing treatment ith BAL suggested to us that a state of latent tetany ight be present, and the detection of Chvostek's sign n both sides confirmed this suspicion. The absence of lkalosis made it probable that the tetany was of low-alcium or low-magnesium type; so we studied the otassium, sodium, calcium, magnesium, and inorganic-hosphate levels in the serum in this and other patients and olunteer students after intramuscular injections of BAL.

TOXICITY OF BAL

nimals

Durlacher et al. (1946) state that the convulsions ollowing BAL are not due to hypoglycæmia. Toxic loses produce a metabolic acidosis, shown by a diminished H and CO_2 content and increased amounts of serum-actic acid and amino nitrogen. The blood-sugar level ises initially but falls to hypoglycæmic levels before leath. The glycogen content of the liver is reduced, and he potassium content of the liver is decreased with ncrease of the sodium and chloride contents.

Modell, Chenoweth, and Krop (1946) give evidence ndicating that the high blood lactic-acid level does not ause the symptoms, and that the eye signs and salivation re produced by BAL in the circulation and not by that the expired air or in the tears. The signs of salivation nd lacrimation also depend on an intact parasympa-hetic innervation. A dose of about $^1/_3$ L.D.50 had no ffect on the prothrombin-time. Post mortem the only nequivocal effects noted were œdema and petechial æmorrhages in the lungs.

Chenoweth (1946) noted a rise in blood-pressure after mall doses of BAL but a fall in systemic and pulmonary rterial pressures after larger doses, with a fall in venous ressure except the portal pressure, which was raised. le concludes that BAL has a primary constricting ction, but that capillary damage from larger doses ads to increased permeability and signs of peripheral ascular failure. A pronounced increase was noted in the ate of lymph-flow from the thoracic and cervical ducts.

Krop (1946) found a considerable accumulation of ictate in the liquid surrounding a stimulated frog's sartorius muscle in the presence of BAL. The initial heat and "twitch tension" were at first increased and later reduced, without significant change in "efficiency."

Man

Sulzberger et al. (1946) studied the toxic effects of BAL injected intramuscularly into 34 healthy young adult males without arsenical or other intoxications. Symptoms were noted 10–30 minutes after the injection of doses equivalent to 3·5–5·5 mg. of BAL per kg. of body-weight daily. No cumulative effects were observed with four doses of about 5 mg. per kg. of body-weight at four-hour intervals, but they were noted when there was only a two-hour interval between the first two injections.

In 11 of the volunteers reducing substances were found in the urine, but other urinary findings were normal. There was no evidence of reduction of the CO_2-combining power of the plasma. Icteric indices were all normal. Respiration-rates increased slightly in 15–20 minutes up to a maximum of 26 per minute. There were significant elevations of the blood-pressure in 30–40 minutes in 14 of 17 volunteers.

In this country the therapeutic dose used has been only about 1·5 mg. per kg. of body-weight (BAL Conference of M.R.C., 1947).

Modell, Gold, and Cattell (1946) studied the effects of BAL on 8 women and 1 man, aged 18–49 years, with secondary or tertiary syphilis. The minimum dose which produced toxic effects was 3–5 mg. per kg. of body-weight. After a single dose of 8 mg. per kg. the symptoms were most severe 5–30 minutes after the injection, increasing gradually in intensity until a level was reached which lasted about 40 minutes, and then subsiding gradually but persisting for between 15 minutes and 2 hours. The blood-pressure and other changes were reversible.

The symptoms of intoxication from BAL as described by these authors, in their exact terms, are compared with the symptoms of latent tetany as described by Strümpell and Seyfarth (1931), with additions from Poulton et al. (1930) as follows:

Toxic symptoms from BAL	*Symptoms of tetany*
Nausea, vomiting	Hypersecretion of gastric juice
Headache	
Burning sensations of the lips, mouth, and throat	Hyperexcitability of the auditory and gustatory nerves
Constricted feelings and pains in the chest	Contractions of the diaphragm
Constricted feelings and pains in the hands, and muscle spasm of the leg	Carpopedal spasm

Births, Marriages, and Deaths

BIRTHS

APPLEBY.—On July 13, at Sheffield, the wife of Captain T Appleby, R.A.M.C.—a son.

COLYER.—On July 15, at Sheffield, the wife of Dr. Thomas C —a son.

CROCKETT.—On July 9, in London, the wife of Dr. Gerard C —a son.

D'ABREU.—On July 10, in Birmingham, the wife of Mr. d'Abreu, O.B.E., F.R.C.S.—a daughter.

FORSTER.—On July 16, at Barnstaple, the wife of Dr. W. M. Fo —a son.

IMRIE.—On July 12, at Guildford, the wife of Dr. D. A. Imrie, M.D.—a daughter.

LE CLERCQ.—On July 13, the wife of Surgeon Lieutenant L le Clercq, R.N.—a daughter.

LOVELOCK.—On July 12, in New York, the wife of Dr. J. E. Lo lock—a daughter.

MARQUIS.—On July 16, in Edinburgh, the wife of Dr. R. M. Marq —a daughter.

SMITH.—On July 16, in London, the wife of Dr. W. H. R. Smith a son.

STANLEY.—On July 15, in London, the wife of Mr. B. E Cra Stanley, F.R.C.S.—a daughter.

THOMSON.—On July 11, at Falmouth, the wife of Dr. Col Thomson, M.C.—a daughter.

TOOHEY.—On July 12, in London, the wife of Dr. M. I. Toohey a daughter.

TYSON.—On July 13, at Singapore, the wife of Dr. W. J. Tyson a son.

VLASTO.—On July 10, at Weymouth, the wife of Dr. Philip Vla —a son.

WALFORD.—On July 10, the wife of Dr. P. A. Walford—a daugh

WHITE.—On July 10, at Berkhamsted, the wife of Dr. Denis White a son.

MARRIAGES

ENZER—DEACON.—On July 8, in London, John Enzer, M.R.C to Margaret Deacon.

KELSEY—SHACKLETON.—On July 12, at Askrigg, Francis K Kelsey, B.M., to Rachel Fell Shackleton, B.M.

ROSE—RANKIN.—On July 10, at Perth, Ian Falconer Rose, M F.R.C.S., to Christian Rankin.

VOWLES—KNOWLES.—On July 17, at Bideford, Keith D John Vowles, M.B., to Mary Knowles, M.B.

DEATHS

FRYER.—On July 14, at Pinner, James Fryer, M.B. Glasg., D.P.H.

GOODHART.—On July 16, in London, Gordon Wilkinson Good M.A., M.D. Camb., F.R.C.P., aged 65.

HICKMAN.—On July 8, at Flax Bourton, Somerset, Henry Rit Belcher Hickman, M.A., B.M. Oxfd, aged 82.

LOUGHNANE.—On July 14, in London, Farquhar McGil Loughnane, F.R.C.S.

LOW.—On July 10, at Tring, Alfred Lees Low, M.B. Edin.

MCCAY.—On July 13, at Woking, David McCay, M.D. Belf., M.R.C lieut.-colonel, I.M.S. retd., aged 75.

O'CONNOR.—On July 12, in Johannesburg, John O'Connor, F.R.C.

SNELLING.—On July 17, at Luton, Trevor Richard Snelling, M.R.C aged 58.

SYKES.—On July 14, at Bath, John Lewis Sykes, M.R.C.S.

LATENT TETANY CAUSED BY BAL

2:3 DIMERCAPTOPROPANOL

BRIAN RUSSELL

LONDON

THE BAL Conference of the Medical Research Council 47) said that BAL is efficacious as an antidote to enicals, forming relatively stable ring compounds h arsenoxides, and thus promoting increased urinary retion of arsenic. It has been used successfully against oxication by mercury (Longcope and Luetscher 46) and gold (Ragan and Boots 1947), and is said to stroy the complexes formed between these metals and dy proteins. In animal experiments it has been found abstract nickel, cadmium, chromium, bismuth, and timony, and it may be capable of withdrawing other etals, including lead. In a patient with chronic lead isoning Telfer (1947) noted a rise of over 100% in inary lead excretion after twelve injections in three ys of 1·9 mg. of BAL per kg. of body-weight. These cts make it likely that BAL can also withdraw certain sential kations from the serum and tissues, for it would strange if all body metals were immune from its fluence.

The occurrence of cramp-like pains in the limbs, and asms of the fingers, in a patient undergoing treatment ith BAL suggested to us that a state of latent tetany ight be present, and the detection of Chvostek's sign both sides confirmed this suspicion. The absence of kalosis made it probable that the tetany was of low-lcium or low-magnesium type; so we studied the otassium, sodium, calcium, magnesium, and inorganic-hosphate levels in the serum in this and other patients and olunteer students after intramuscular injections of BAL.

TOXICITY OF BAL

nimals

Durlacher et al. (1946) state that the convulsions llowing BAL are not due to hypoglycæmia. Toxic oses produce a metabolic acidosis, shown by a diminished H and CO_2 content and increased amounts of serum-actic acid and amino nitrogen. The blood-sugar level ises initially but falls to hypoglycæmic levels before eath. The glycogen content of the liver is reduced, and he potassium content of the liver is decreased with ncrease of the sodium and chloride contents.

Modell, Chenoweth, and Krop (1946) give evidence dicating that the high blood lactic-acid level does not ause the symptoms, and that the eye signs and salivation re produced by BAL in the circulation and not by that the expired air or in the tears. The signs of salivation nd lacrimation also depend on an intact parasympa-hetic innervation. A dose of about $^1/_3$ L.D.50 had no fect on the prothrombin-time. Post mortem the only nequivocal effects noted were œdema and petechial æmorrhages in the lungs.

Chenoweth (1946) noted a rise in blood-pressure after mall doses of BAL but a fall in systemic and pulmonary rterial pressures after larger doses, with a fall in venous ressure except the portal pressure, which was raised. Ie concludes that BAL has a primary constricting ction, but that capillary damage from larger doses eads to increased permeability and signs of peripheral ascular failure. A pronounced increase was noted in the ate of lymph-flow from the thoracic and cervical ducts.

Krop (1946) found a considerable accumulation of actate in the liquid surrounding a stimulated *frog's sartorius muscle in the presence of* BAL. The initial heat and "twitch tension" were at first increased and later reduced, without significant change in "efficiency."

Man

Sulzberger et al. (1946) studied the toxic effects of BAL injected intramuscularly into 34 healthy young adult males without arsenical or other intoxications. Symptoms were noted 10–30 minutes after the injection of doses equivalent to 3·5–5·5 mg. of BAL per kg. of body-weight daily. No cumulative effects were observed with four doses of about 5 mg. per kg. of body-weight at four-hour intervals, but they were noted when there was only a two-hour interval between the first two injections.

In 11 of the volunteers reducing substances were found in the urine, but other urinary findings were normal. There was no evidence of reduction of the CO_2-combining power of the plasma. Icteric indices were all normal. Respiration-rates increased slightly in 15–20 minutes up to a maximum of 26 per minute. There were significant elevations of the blood-pressure in 30–40 minutes in 14 of 17 volunteers.

In this country the therapeutic dose used has been only about 1·5 mg. per kg. of body-weight (BAL Conference of M.R.C., 1947).

Modell, Gold, and Cattell (1946) studied the effects of BAL on 8 women and 1 man, aged 18–49 years, with secondary or tertiary syphilis. The minimum dose which produced toxic effects was 3–5 mg. per kg. of body-weight. After a single dose of 8 mg. per kg. the symptoms were most severe 5–30 minutes after the injection, increasing gradually in intensity until a level was reached which lasted about 40 minutes, and then subsiding gradually but persisting for between 15 minutes and 2 hours. The blood-pressure and other changes were reversible.

The symptoms of intoxication from BAL as described by these authors, in their exact terms, are compared with the symptoms of latent tetany as described by Strümpell and Seyfarth (1931), with additions from Poulton et al. (1930) as follows:

Toxic symptoms from BAL	*Symptoms of tetany*
Nausea, vomiting	Hypersecretion of gastric juice
Headache	
Burning sensations of the lips, mouth, and throat	Hyperexcitability of the auditory and gustatory nerves
Constricted feelings and pains in the chest	Contractions of the diaphragm
Constricted feelings and pains in the hands, and muscle spasm of the leg	Carpopedal spasm
Conjunctivitis, "tearing," blepharospasm, and burning sensations of the eyes	Recurring conjunctivitis
Rhinorrhœa and burning or tingling of the nose	
Salivation and pains in the jaws	Salivation
Tingling of the hands, pains in the limbs, burning and tingling of the extremities and of the skin, and burning sensation of penis	Paræsthesiæ and pains
Sweating of forehead, hands, &c., and sense of warmth	Hypersecretion of sweat
Moderate to very severe abdominal pain	Painful spasms of diaphragmatic or other muscles of the abdomen, chest, or back
Tremor, general agitation, unrest	Tremors, convulsions in children
Weakness, fatigue	Muscular weakness
Uncontrollable laughter	Occasional hallucinations
Heart-rate moderately accelerated	Pulse increased
Significant rise of systolic and diastolic blood-pressure $^1/_2$ hour after injection, persisting for 15–90 minutes	Increased cardiac activity and vascular spasm

These symptoms and signs, in both conditions, may be summarised as manifestations of increased excitability of motor, sensory, and secretory nerves, the vegetative nervous system, and the higher centres.

CAUSES OF TETANY

The maintenance in the pericellular fluid of equilibrium between calcium, magnesium, and hydrogen ions on the one hand, and sodium, potassium, and hydroxyl ions on the other, is vital for the health of the cells controlling the heart-beat, the contractility of plain and striped muscle, and the transference of impulses at the neuro-muscular junctions and through synapses. Tetany is produced by increased nervous irritability resulting from a fall in calcium, magnesium, or hydrogen-ion concentration or a rise in that of sodium, potassium, or hydroxyl. Reverse changes lessen nervous irritability and alleviate tetany.

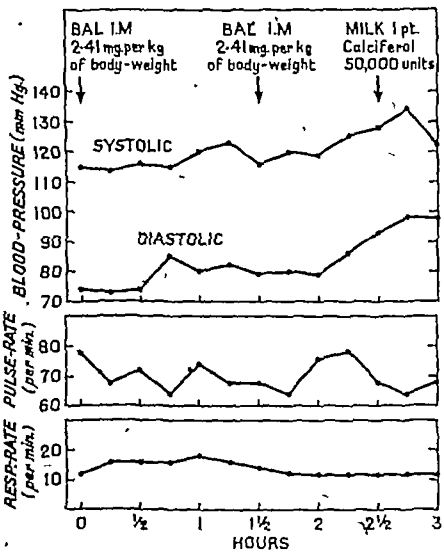

Fig. 1—Blood-pressure and respiration-rate after injection of BAL.

The more common known causes of tetany are (1) alkalosis, particularly from vomiting, excessive alkali ingestion, or hyperventilation, and (2) states of calcium insufficiency. In cattle, a deficiency of magnesium may also produce tetany ("grass tetany"), and Miller (1944) described a boy aged $3^1/_2$ years with osteochondritis who had had tetany since the age of 7 months but whose serum-calcium level was repeatedly within normal limits. The serum-magnesium content was 1·7 mg. per 100 ml., the low limit of normal. Magnesium sulphate grains 5 t.d.s. by mouth relieved the tetany, but there was a relapse on its withdrawal, with Chvostek's and Trousseau's signs present and a serum-magnesium level of 0·6 mg. per 100 ml.

ACTION OF BAL ON MAGNESIUM

In the extensive literature on BAL no reports have been found of any effect on calcium, but Webb and van Heyningen (1947), trying to explain its toxicity, noted its action on many enzymes in vitro and concluded that BAL probably acts as an antagonist of metal activation of enzymes, even interfering with the activation of enzymes activated by Mg^{++} enzymes—e.g., hexokinase. This effect was immediately reversed by the addition of excess Mg^{++}. They thought it an open question whether the toxicity of BAL is due to this inhibition of metal-containing enzymes, and noted further that, though BAL forms stable insoluble compounds with copper and iron, none are formed with Zn^{++} or Mg^{++} at neutral pH.

Barron et al. (1947) state that BAL combines with magnesium to form colourless soluble compounds, which may explain the inhibitory effect of magnesium chloride on the rate of oxidation of 'Dithiol,' noted to be 44% with 0·01 M.$MgCl_2$.

Calcium also forms no insoluble compounds with BAL in vitro.

CASE-RECORD

Our patient was a man aged 57, who had rheumatoid arthritis for twenty months.

He had received nine injections of 'Myocrysin' at intervals, starting about May 1, 1947. The clefts of fingers began to itch after the seventh injection, and a spread rash developed about a week after the last inj In mid-July he had received eight injections of thiosulphate on alternate days, with some relief of the it and of the rash, but these soon relapsed more extensi than before.

Early in August he had been given a course of BAL 400 in the first twenty-four hours in four doses of 100 mg an 200 mg. on each of the second, third, and fourth days in doses a day, and 100 mg. a day for two more days in a daily dose. While undergoing this treatment he had cramps in the shoulders and legs, with fixation of the in flexion, lasting twenty-four hours. His left hand and f arm had become stiff and cramped on about four occasio for a minute or two, the index and middle fingers becom "stuck together" and having to be forced apart with t other hand. His hands had tingled, there had been profu sweating and shivering, and he had vomited once. The ra almost cleared but recurred about a fortnight later, and h was admitted to St. Bartholomew's Hospital on Oct 3 1947, with a polymorphic urticarial, erythematous, and exfoliative eruption.

He was given BAL for four days, 200 mg. daily, in doses of 100 mg. His weight was 9 st. 11 lb., which means a daily dosage of 3·21 mg. per kg. of body-weight. He also received four daily injections of 2 ml. of 'Anahæmin.'

On Nov. 5, three days after the last injection, he had a positive Chvostek's sign on both sides, but Trousseau's sign was absent. Next day the serum-calcium level was 9·5 mg per 100 ml., and the alkali reserve was 62·4 ml. of CO_2 per 100 ml. of serum. Six days later the serum-calcium level wa 10 mg. per 100 ml., and the serum inorganic phosph level 3·8 mg. per 100 ml. The urine revealed no abnorma on routine examination, and a histamine test-meal a hyperchlorhydric response.

Blood-count: red cells 4,570,000 per c.mm., Hb 8 (11·6 g. per 100 ml.), colour-index 0·9, white cells 9000 p c.mm. (polymorphs 80%, lymphocytes 15%, monocytes 1 eosinophils 3%, basophils 1%).

Serum Tests.—Serum-bilirubin (van den Bergh) dir negative, indirect 0·3 mg. per 100 ml. of serum. Takata-A negative. Serum-proteins: total 6 mg. per 100 ml., album 3·8 mg. per 100 ml., globulin 2·2 mg. per 100 ml. Serum alkaline phosphatase 3·8 units.

CLINICAL STUDY

Fifteen days after the last injection of BAL this patient attended again for serum-calcium and other studies before and after injections of BAL.

The test began at 2 P.M. and was preceded by a normal luncheon of meat and vegetables, boiled celery, stewed apples, and macaroni. This was considered unlikely to have any

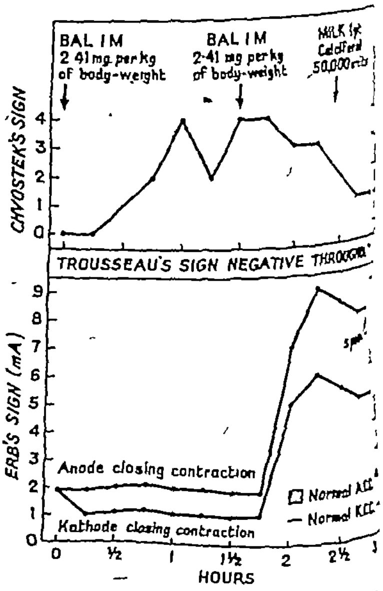

Fig. 2—Nervous signs after injection of BAL. 1, positive unilateral; 2, positive bilateral; 3, strongly positive on one side, positive the other; 4, strongly positive bilateral.

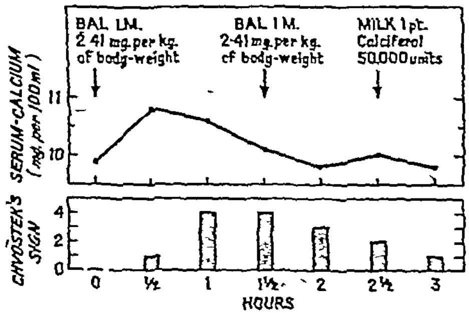
ant effect on the serum-calcium level, since man s calcium principally from milk, cheese, butter, green vegetables, and nuts (Hunter 1931). um salts, whether soluble or insoluble, given by h, appear to be absorbed only with difficulty, and alcium in food is probably entirely converted by tion into the inorganic form and absorbed as um salts, partly or completely ionised.

. 1 shows that the systolic blood-pressure rose 9 mm. Hg and the diastolic blood-pressure by m. Hg after *two injections* of BAL each of 150 mg. /₂ hours' interval. Three blood-pressure readings were n on each occasion and the mean recorded. In the hour of study increasing difficulty was found in the mination of the diastolic pressure after the first of three readings, unless an interval was allowed before ng to record another reading. This difficulty was ght to be due to arterial spasm, particularly since m was also noted in voluntary muscle from vanism at 3 hours. Variations in pulse-rate and piration-rate were not significant.



3—Serum-calcium level and Chvostek's sign after injection of BAL : same notation for Chvostek's sign as in fig. 2.

Chvostek's sign (fig. 2) became positive half an hour er the first injection and remained positive throughout remainder of the test. Trousseau's sign was negative oughout.

With galvanism, the kathode closing contraction and anode closing contraction were within normal limits 1³/₄ hours, but at 2 hours (half an hour after the second ection) rose sharply to a maximum of 6 mA and 9 mA pectively, and afterwards tended to fall slowly but re still 5 mA and 8 mA respectively at the end of the riod of study, with spasm reported in the anode sing contraction at 3 hours. These changes are the posites of those to be expected with tetany, but they e evidence of a profound disturbance in kationic uilibrium, and may be related to the accumulation lactic acid in the muscles, noted in animal studies by op (1946).

In a study of this kind a single estimation of the um-calcium and serum-magnesium levels is of relaely little value, and only indirect evidence of fluctuans in the tissue calcium and magnesium content be obtained by a series of serum estimations at suite intervals. It must be emphasised that tetany ends on the ionic state of the tissues, which probably ves in parallel with that of the serum and is theree effectively indicated by serum estimations. In the normal conditions created by an injection of BAL, cium ions, if withdrawn from the tissues, must pass o the serum, leading to the paradox of tetany *in the* sence of a high serum-calcium level.

The serum-calcium level (fig. 3) showed a preliminary of 0·9 mg. per 100 ml. in the first half-hour after the ection, followed by a *steady slow fall* and a smaller after the second injection, with a further tendency fall apparent in the last reading. Chvostek's sign, orded beneath the curve in column form, became maximal 1–1¹/₂ hours after the injection. An analys of the findings of Bennett et al. (1932) concerning physica signs and average serum-calcium estimations in 1 patients with idiopathic steatorrhœa suggests that laten tetany causing small depressions of the tissue calciun is more likely to give a positive Chvostek's sign than i overt tetany causing large depressions, whereas witl Trousseau's sign the opposite applies :

	History of acute tetany (10 cases)	*No history of acute tetany (5 cases)*
Serum-calcium ..	(5 1–9 0 mg. per 100 ml.)	(8 0–10 1 mg. per 100 ml.)
Average serum-calcium ..	7·66 mg. per 100 ml.	9 12 mg. per 100 ml.
Chvostek's sign..	5 positive ; 6 negative	4 positive ; 1 negative
Trousseau's sign..	6 positive ; 4 negative	None positive ; 5 negative

The rise in serum-calcium level in *the present* case in the absence of a *high-calcium diet*, suggests a withdrawal of calcium from the tissues into the blood at rate faster than its excretion. The period of study of thi *patient* was insufficient to reveal the later effects of BAI

In view of the sharp depression of nervous irritabilit towards the end of the test it was thought possible tha sodium was depleted at this time, but only insignifican changes in serum-sodium were detected (table II).

FURTHER STUDIES OF TOXICITY

The toxicity of BAL has been studied in 13 person receiving doses between 0·75 and 6·11 mg. per kg. c body-weight, and *the* results are recorded in *table* I.

There were no symptoms in case 5 (untreated gol dermatitis). All the other persons injected had toxi manifestations ; but, *in relation to* dosage, *these* wer *minimal* in case 11 (untreated arsenical dermatitis when given 6·11 mg. per kg. of body-weight. Thes observations suggest that, if there is an affinity betwee BAL and magnesium or calcium it is weaker than tha *between* BAL and gold *or* arsenic.

Difficulty was often experienced in the withdrawa of samples of venous blood 2–6 hours after the injection and *in inserting* the needle into the vein, and this wa *thought to* be due to venous spasm. *This difficult* was not noted in obtaining blood samples from control *previously injected* with 10% benzyl benzoate in arachi oil.

Serial serum chemical studies were made in 11 person (table II). We have *not found in* the literature *informatio* about the hour-by-hour variations throughout the da in calcium, magnesium, and phosphate levels in norma persons, and it is possible that the calcium figure recorded here represent fluctuations within norma *limits.* This seems less probable, however, for the rela tively greater changes *in* serum-magnesium. *The* calciun figures were somewhat equivocal but sometimes (case 6, 7, and 9) suggested *that* calcium had been withdraw from the tissues to the serum. On *the* other hand, case 10 who received 5·71 mg. of BAL *per* kg. *of body-weight* showed *minimal serum*-calcium changes though he ha severe pains, cramps, and parœsthesiæ and develope Chvostek's and Trousseau's signs. *Unfortunately* hi serum-magnesium was *not studied.* The maximum chang in serum-calcium level was about 10%. Since the control showed changes of up to 7·5%, though often in th opposite direction, *this* variation probably *cannot* b regarded as significant.

In 4 cases magnesium studies revealed changes o 65%, 50%, 24%, and 11% in the serum-magnesium level. Magnesium studies in two controls showed changes of 18% and 11%.

In 2 patients the serum-inorganic phosphorus was estimated and was found to vary by 26% and 21%. The changes in serum-potassium (3%) and serum-sodium

These symptoms and signs, in both conditions, may be summarised as manifestations of increased excitability of motor, sensory, and secretory nerves, the vegetative nervous system, and the higher centres.

CAUSES OF TETANY

The maintenance in the pericellular fluid of equilibrium between calcium, magnesium, and hydrogen ions on the one hand, and sodium, potassium, and hydroxyl ions on the other, is vital for the health of the cells controlling the heart-beat, the contractility of plain and striped muscle, and the transference of impulses at the neuro-muscular junctions and through synapses. Tetany is produced by increased nervous irritability resulting from a fall in calcium, magnesium, or hydrogen-ion concentration or a rise in that of sodium, potassium, or hydroxyl. Reverse changes lessen nervous irritability and alleviate tetany.

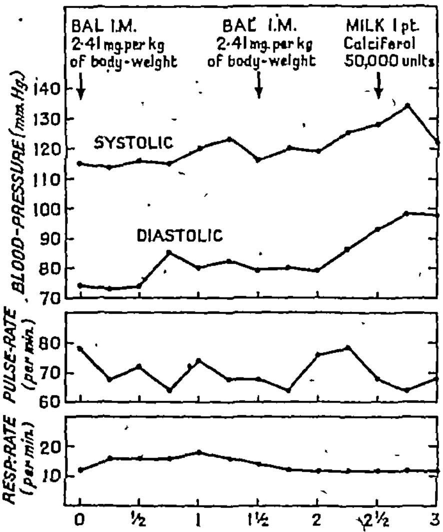


Fig. 1—Blood-pressure and respiration-rate after injection of BAL.

The more common known causes of tetany are (1) alkalosis, particularly from vomiting, excessive alkali ingestion, or hyperventilation, and (2) states of calcium insufficiency. In cattle, a deficiency of magnesium may also produce tetany ("grass tetany"), and Miller (1944) described a boy aged $3^1/_2$ years with osteochondritis who had had tetany since the age of 7 months but whose serum-calcium level was repeatedly within normal limits. The serum-magnesium content was 1·7 mg. per 100 ml., the low limit of normal. Magnesium sulphate grains 5 t.d.s. by mouth relieved the tetany, but there was a relapse on its withdrawal, with Chvostek's and Trousseau's signs present and a serum-magnesium level of 0·6 mg. per 100 ml.

ACTION OF BAL ON MAGNESIUM

In the extensive literature on BAL no reports have been found of any effect on calcium, but Webb and van Heyningen (1947), trying to explain its toxicity, noted its action on many enzymes in vitro and concluded that BAL probably acts as an antagonist of metal activation of enzymes, even interfering with the activation of enzymes activated by Mg^{++} enzymes—e.g., hexokinase. This effect was immediately reversed by the addition of excess Mg^{++}. They thought it an open question whether the toxicity of BAL is due to this inhibition of metal-containing enzymes, and noted further that, though BAL forms stable insoluble compounds with copper and iron, none are formed with Zn^{++} or Mg^{++} at neutral pH.

Barron et al. (1947) state that BAL combines with magnesium to form colourless soluble compounds, which may explain the inhibitory effect of magnesium chloride on the rate of oxidation of 'Dithiol,' noted to be 44% with 0·01 M.$MgCl_2$.

Calcium also forms no insoluble compounds with BAL in vitro.

CASE-RECORD

Our patient was a man aged 57, who had rheumatoid arthritis for twenty months.

He had received nine injections of 'Myocrysin' at intervals, starting about May 1, 1947. The clefts of fingers began to itch after the seventh injection, and a spread rash developed about a week after the last inje In mid-July he had received eight injections of thiosulphate on alternate days, with some relief of the it and of the rash, but these soon relapsed more extensi than before.

owel is affected by the use of BAL, but this has not been arried out.

Electrocardiographic studies of this patient and ase 8 (table I) revealed no appreciable difference after he injection of BAL. The changes said to develop in ypoparathyroidism—a lengthening of systole and an ncrease of the Q-T interval from the normal of 0·3 *to* ·6 sec. (Rose 1943) with a low R and relatively high T vave (Zondek 1935 citing Schiff 1923)—were not bserved.

Fantl and Nance (1947), using Quick's (1938) technique, report inhibition of coagulation from prothrombin inactivation by BAL in vitro, not confirmed in vivo, no change being found in whole-blood coagulation-time or prothrombin activity at 1 and 2½ hours after the injection. Further, no change was noted in the coagulation-time when clotting was caused by the addition of thrombin. This difference of in-vitro and in-vivo findings might be explained by BAL's removal of part of the added calcium chloride from availability before it can react with prothrombin and thromboplastin to form thrombin.

The coagulation-time was studied by the method of Dale and Laidlaw in case 2, a psoriatic volunteer, both after an injection of 4 ml. of 10% benzyl benzoate in arachis oil and after 4 ml. of BAL representing 2·62 mg. per kg. of body-weight. The changes were regarded as too slight to be significant.

(Time in minutes and seconds)

In an attempt to demonstrate skeletal changes radiographically two guineapigs were given injections of BAL averaging 29 and 16 mg. per kg. of body-weight daily for six weeks, a guineapig of similar age and size being used as control. No change in the bones was detected.

DISCUSSION

Clinically the symptoms and signs of BAL intoxication are identical with those of latent tetany. Experiments on animals have shown that some of the symptoms depend on parasympathetic innervation (Modell, Chenoweth, and Krop 1946) while increased "twitch tension" and the accumulation of lactate give evidence of increased muscular activity (Krop 1946).

That the tetany is not due to alkalosis is shown by our patient's normal alkali reserve and by the finding of metabolic acidosis in experiments on animals (Durlacher et al. 1946). Tetany might, however, arise from disturbance in pericellular ionic equilibrium between calcium and magnesium on the one hand, and sodium and potassium on the other. The changes in serum-magnesium in the 4 cases studied are relatively greater than those in serum-calcium found in any of the 11 persons. Nevertheless the changes in serum-inorganic phosphorus are by no means insignificant and may be related to some disturbance in calcium.

This incomplete study suggests that BAL has a selective influence on gold and arsenic far greater than on magnesium, and probably much greater on magnesium than on calcium. In the absence of metallic intoxications it may interfere with magnesium, and perhaps also calcium, metabolism. Attempts are being made to confirm or refute this theory of the cause of the latent tetany by intravenous injections of calcium gluconate or magnesium sulphate, in the presence of toxic symptoms. Patients receiving BAL might be included with those suffering from other conditions qualifying for extra milk.

The daily dose of 3 mg. per kg. recommended in this country appears unlikely to give trouble over short periods of treatment. On the other hand we have recently seen a patient who, while under treatment with BAL for arsenical dermatitis, developed somewhat rapidly symptoms of general paralysis of the insane. Since BAL not only removes arsenic but also seems to have an exciting influence on nervous tissue, it may perhaps provoke latent neurosyphilis into activity.

The increased risk of tetany in pregnancy is apparent, since Bogert and Plass (1923) found that the average calcium was 9·1 mg. per 100 ml. for 23 women at the time of labour, and 10·2 mg. for 12 normal non-pregnant women.

Control studies have not been made on potassium, sodium, and inorganic phosphorus. Potassium, being mainly intracellular, would be least likely to be affected.

If BAL has an affinity for calcium or magnesium it is likely to attract: serum-calcium or serum-magnesium ions, and serum-calcium or serum-magnesium loosely attached to plasma-protein, and to render these forms unavailable to the organism though still present in the blood. It is also likely to deplete the pericellular spaces of calcium or magnesium ions, and calcium or magnesium attached to protein; or the calcium and magnesium in this situation may only be rendered unavailable and not withdrawn, leading to steady serum-calcium and serum-magnesium levels.

On the hypothesis that BAL causes withdrawal of available calcium or magnesium from the blood and the tissues various possibilities may be considered. Where calcium is mentioned, similar possibilities for magnesium are to be inferred.

(1) If the withdrawal of calcium from the tissues is faster than the excretion of BAL with the calcium attached to it, there will be a rise in serum-calcium. If the rate of withdrawal is equal to the rate of excretion, there will be no apparent change in serum-calcium. If the excretion is more rapid than the withdrawal from the tissues, there will be a fall in serum-calcium.

(2) Whatever the primary change in serum-calcium, if the *displaced tissue calcium and BAL-attached serum-calcium* continue to be excreted, there must next follow a fall in serum-calcium, because it may be assumed that the flow from tissues to serum drops off before the excretion of the accumulated serum calcium is complete.

(3) The effect of BAL on the calcium in the bones must also be considered. It seems unlikely that it will cause a direct withdrawal of calcium from the bones; but, if the tissues are depleted of calcium, there must be a rapid withdr of calcium from the bones and teeth to replen vital kation deficiency.

In 6 cases the serum-calcium was higher (up to mg. per 100 ml.) 24 hours after the injection than be but in the 2 persons receiving the highest doses this not so. If, in fact, this secondary rise is due to withd of the calcium from the bones, it might be exp that there would be a parallel rise in the serum-inorg phosphate.

Kruse et al. (1933) state that magnesium defic is without apparent effect on the inorganic phosph content of the blood. Since magnesium ions are to activate bone phosphatase (which is inhibited inorganic phosphate), it seems essential for the well-be of the organism that this element should not be drawn from the bones. Changes in the serum-magnes in 2 patients studied were, however, associated changes considered significant in serum-inorganic phosphate. It follows that the rise in level of inorg phosphate may be related to changes in the tissue calc

According to Shohl (1939) 99·6% of the calc but only 57·9% of the magnesium in the body in the bones, whereas the total muscle content magnesium 6 g. and calcium 2 g. The rise in serum magnesium (up to 65%) after the injection is consistent with the relatively higher muscle-magnesium content as compared with calcium.

The urinary calcium excretion in one patient (case 5) showed hardly any change after a single dose of 200 mg. of BAL: 0·170 g. of calcium was excreted in the urine in the 24 hours before the injection, and 0·188 g in the 24 hours after it. A calcium-balance test is necessary to demonstrate whether the calcium excretion from

owel is affected by the use of BAL, but this has not been arried out.

Electrocardiographic studies of this patient and ase 8 (table I) revealed no appreciable difference after he injection of BAL. The changes said to develop in ypoparathyroidism—a lengthening of systole and an ncrease of the Q-T interval from the normal of 0·3 to ·6 sec. (Rose 1943) with a low R and relatively high T rave (Zondek 1935 citing Schiff 1923)—were not bserved.

Fantl and Nance (1947), using Quick's (1938) technique, eport inhibition of coagulation from prothrombin nactivation by BAL in vitro, not confirmed in vivo, no hange being found in whole-blood coagulation-time or prothrombin activity at 1 and 2½ hours after the injection. Further, no change was noted in the coagulation-time when clotting was caused by the addition of thrombin. This difference of in-vitro and in-vivo findings might be explained by BAL's removal of part of the added calcium chloride from availability before it can react with prothrombin and thromboplastin to form thrombin.

The coagulation-time was studied by the method of Dale and Laidlaw in case 2, a psoriatic volunteer, both after an injection of 4 ml. of 10% benzyl benzoate in arachis oil and after 4 ml. of BAL representing 2·62 mg. per kg. of body-weight. The changes were regarded as too slight to be significant.

	Before test	*1/2 hr.*	*1 hr.*	*2 hr.*	*3 hr.*	*4 hr.*	*5 hr.*	*6 1/2 hr.*
Control	2·15	—	1·40	2·14	1·20	1·46	1·52	1·36
BAL	1·12	1·32	1·22	1·59	1·42	1·55	2·07	2 06

(Time in minutes and seconds)

In an attempt to demonstrate skeletal changes radiographically two guineapigs were given injections of BAL averaging 29 and 16 mg. per kg. of body-weight daily for six weeks, a guineapig of similar age and size being used as control. No change in the bones was detected.

DISCUSSION

Clinically the symptoms and signs of BAL intoxication are identical with those of latent tetany. Experiments on animals have shown that some of the symptoms depend on parasympathetic innervation (Modell, Chenoweth, and Krop 1946) while increased "twitch tension" and the accumulation of lactate give evidence of increased muscular activity (Krop 1946).

That the tetany is not due to alkalosis is shown by our patient's normal alkali reserve and by the finding of metabolic acidosis in experiments on animals (Durlacher et al. 1946). Tetany might, however, arise from disturbance in pericellular ionic equilibrium between calcium and magnesium on the one hand, and sodium and potassium on the other. The changes in serum-magnesium in the 4 cases studied are relatively greater than those in serum-calcium found in any of the 11 persons. Nevertheless the changes in serum-inorganic phosphorus are by no means insignificant and may be related to some disturbance in calcium.

This incomplete study suggests that BAL has a selective influence on gold and arsenic far greater than on magnesium, and probably much greater on magnesium than on calcium. In the absence of metallic intoxications it may interfere with magnesium, and perhaps also calcium, metabolism. Attempts are being made to confirm or refute this theory of the cause of the latent tetany by intravenous injections of calcium gluconate or magnesium sulphate, in the presence of toxic symptoms. Patients receiving BAL might be included with those suffering from other conditions qualifying for extra milk.

The daily dose of 3 mg. per kg. recommended in this country appears unlikely to give trouble over short periods of treatment. On the other hand we have recently seen a patient who, while under treatment with BAL for arsenical dermatitis, developed somewhat rapidly symptoms of general paralysis of the insane. Since BAL not only removes arsenic but also seems to have an exciting influence on nervous tissue, it may perhaps provoke latent neurosyphilis into activity.

The increased risk of tetany in pregnancy is apparent, since Bogert and Plass (1923) found that the average calcium was 9·1 mg. per 100 ml. for 23 women at the time of labour, and 10·2 mg. for 12 normal non-pregnant women.

SUMMARY

A case is reported in which latent tetany developed during intramuscular administration of BAL.

Studies of 13 patients and volunteers receiving doses of BAL between 0·75 and 6·11 mg. per kg. of body-weight revealed, besides toxic symptoms, a positive Chvostek's sign in 7, of whom 1 also had a positive Trousseau's sign. Of the remainder, 5 had cramps and other toxic symptoms, and 1 was free from symptoms.

Serum studies suggest that the tetany may be of low-magnesium and possibly also of low-calcium type, either from these kations being rendered unavailable to the cells or being removed attached to BAL.

All the symptoms of toxicity from BAL are capable of explanation as latent tetany. Calcium-balance and magnesium-balance studies are necessary to explain the metabolic disturbances.

In doses of 3·14 mg. per kg. of body-weight daily for four days BAL gives great relief to sufferers from arsenic, gold, and mercury intoxications, and the danger of a temporary unavailability of pericellular calcium and magnesium can be ignored if the patient is provided with a high-calcium diet, magnesium sulphate, and vitamin D.

The serum-sodium and serum-potassium levels were not appreciably affected by the injection of BAL.

In 5 controls injected with 10% benzyl benzoate in arachis oil in volumes equivalent to those used in giving between 1·31 and 4·62 mg. of BAL per kg. of body-weight, no symptoms of latent tetany developed, but 1 had a doubtfully positive Chvostek's sign $1^1/_2$ hours after the injection.

Acknowledgments are due to colleagues in the pathological, physiotherapeutic, cardiographic, and X-ray departments for their help, and in particular to Mr. Ralph Hudson for his blood estimations, and to the student volunteers.

"... Security with regard to avoidance of war cannot be assured by purchase of military equipment or any amount of research in applications of physical and biological science to military technology. . . . The entire documented history of man stresses the danger and folly of such reliance. The only way to security in international relations lies in a devotion to study of the social problems confronting mankind as a whole. This calls for an undreamed of development of all the social sciences and their application to social problems in a spirit of high responsibility. It calls for an approach to such problems which is not limited by traditional thinking in terms of group rivalries of any kind. It will not be easy, just as it is not easy to develop supersonic jet planes and guided missiles."—E. U. CONDON, director, National Bureau of Standards, Washington, *Science*, June 25, p. 665.

TREATMENT OF TUBERCULOSIS WI SULPHETRONE

D. G. MADIGAN
B.A., M.B. N.U.I.
SENIOR TUBERCULOSIS OFFICER, KENT
From the Tuberculosis Chemotherapy Unit, County Hospital, Farnborough, Kent

'SULPHETRONE' was shown by Brownlee et al. (19 to be antituberculotic, and subsequently Brownlee and Kennedy (1948a) demonstrated its efficiency in protecting animals against experimental tuberculous infection. The pharmacological evidence pointed to low toxicity and suggested its suitability for administration to man over long periods at blood-levels likely to prove bacteriostatic to tubercle bacilli.

In 1943 a clinical trial of sulphetrone was organised and developed in this hospital. The choice of clinical material was dictated solely by its presentation within the hospital; thus it represents a statistically unselected population drawn on for five years. Pulmonary cases predominated, but all kinds of tuberculosis were included. It was impracticable to devise a controlled experiment in the sense of a side-by-side comparison, chiefly because of the impossibility of predicting the course of tuberculosis in apparently similar cases, but also because the patient must unquestionably be granted the advantages of orthodox active therapy. In the present series of 70 cases, when due regard has been paid to all available conservative and mechanical aids, assessment depends on experienced clinical judgment.

MANAGEMENT

Since an effective level of sulphetrone has to b maintained in blood and other tissues for a very time, management assumes major importance. comprehensive pharmacological study by Brownlee (1948) going forward simultaneously enabled difficulties to be anticipated or recognised at an e stage. Some, such as the development of the blood-l and variations in absorption and excretion, first arose clinical problems. Attention was also drawn to th patient's nutrition, the blood-picture proving of particula value in this connexion. Where nutritional imbala was detected, the necessary correctives were applied. From the solution of these early difficulties the follow scheme of management evolved.

Preliminary Nutrition

Routine investigations showed tuberculous patients in general to be poorly nourished, a fact widely recognised (Braverman 1938, 1942). A frequent manifestation w secondary anæmia, which may assume major importa in view of the capacity of sulphetrone to interfere w biosynthesis in the gut (Brownlee et al. 1948). Subcli liver dysfunction may be uncovered by drug thera it may be anticipated and tested for by repeated bilir estimates, which in my experience constitute the suitable liver-function test for this purpose. After in blood analyses and differential white-cell counts a co of ferrous sulphate gr. 3 by mouth three times d together with fresh brewers' yeast 2 drachms daily, given for a fortnight before and throughout sulphetr therapy. It is important that the yeast should be brew yeast and, to obtain full value from it, the cells sh be ruptured by heating the yeast in milk nearly boiling-point, and giving it as soon as it is c enough to drink. This regimen makes good the hy chromic anæmia and the nutritional anæmia caused sulphetrone.

A third form of anæmia, hæmolytic anæmia, devel and continues throughout the administration of sulph trone; it is responsible for a reduction in hæmoglob level as low as 60% (Haldane). Should the hæmo- in level fall below this figure, sulphetrone should be ndrawn. This hæmolytic anæmia is rarely seen when and yeast are given: its presence indicates a ificant nutritional deficiency. Yeast also prevents the t of a peripheral neuritis, otherwise occasionally seen. ith continued pyrexia the patient may be in negative ogen balance: usually there is a ready response to mic animal-protein hydrolysate, combined with ohydrate, of each 1 g. per kg. of body-weight daily.

Rest

ice the immediate effect of exhibiting sulphetrone e imposition of an additional load on the patient, bed rest in the case of acute or subacute lesions is sary. Less severe discipline is needed with chronic ns, and outpatient therapy may be practised in the nce of constitutional disturbance.

ge and Blood-level

ownlee and Kennedy (1948a and b) showed that eapigs could be protected against tuberculosis by ntaining blood-sulphetrone levels of 5–6 mg. per ml. It seemed logical to raise this level in man ards the highest limits of tolerance, and concentra- s of 7·5–10 mg. per 100 ml. were aimed at. Clinical erience showed that massive initial doses were not tolerated; so a schedule of gradually increasing s was adopted. A suitable initial dose for adults 5 g. daily (0·5 g. eight-hourly) for the first week, and daily (0·5 g. four-hourly) for the second. Thereafter daily dose is increased by 1–2 g. each week until apeutic blood-sulphetrone levels are reached, usually a dose of 6–10 g. daily. To ensure undisturbed rest ight two four-hourly doses are omitted and the last ning and the first morning doses are doubled. For dren up to the age of 3 years an initial dose of 0 5 g. y, followed by 1 g. in the second week, is recom- ded; in children aged 4–10 years the initial dose is . and thereafter the dose is increased as for adults; ldren aged 11–15 may receive full adult dosage.

Vhen it is desirable to administer sulphetrone intra- scularly combined with streptomycin for miliary erculosis or for tuberculous meningitis, 0 05 g. per of body-weight every four to six hours for the first nty-four hours is suitable. This dosage should be ed, after the blood-sulphetrone level has been mated, to 0·1 g. per kg. of body-weight during the ond twenty-four hours. There is some evidence that, en the meninges are involved, blood-sulphetrone levels ve 5 mg. per 100 ml. may cause vomiting.

Besides a weekly check of red cells and hæmoglobin re should be a weekly estimate of blood-sulphetrone. table methods have been described by Brownlee et al. 48). Renal clearance of sulphetrone is rapid, and total y fluids should be restricted to three pints to maintain adequate level of sulphetrone in the tissues, since the the fluid intake the greater the saturation with hetrone. Conversely, clearance of sulphetrone is elerated by raising fluid intake. Climatic conditions ct the sulphetrone level in the tissues for the same on. The blood-level should not exceed 12·5 mg. 100 ml.; this level allows little margin of safety, sulphetrone must be temporarily discontinued if s exceeded. If, on withdrawal of sulphetrone, levels ve this figure are still found, fluids should be pushed all routes, and enemas given. No major catastrophe o be expected unless levels above 12·5 mg. per 100 ml. sist for several days.

icity

he first three weeks of sulphetrone therapy are a iod of physiological readjustment. Minor symptoms slight headache, difficulty in reading and in concen- tion, temporary depression, and nausea. Blueness of skin and mucosæ is often observed at this initial stage during a period of low dosage. These manifestations call for no treatment other than reassurance. Adjustment is quicker in young people and children, and slower in the older age-groups and in those with diminished vital capacity. The blueness is believed to be associated with disturbance of the alkali reserve. The symptoms are alleviated by sodium bicarbonate and less effectively by other alkalis.

Moderate or severe continuous headache, loss of appetite, nausea and vomiting, gastro-intestinal discomfort, dizziness, and mental confusion are danger signals. These conditions are associated with high blood-sulphetrone levels; therefore measures should be initiated to hasten elimination of sulphetrone. It should be remembered that there is always a substantial reservoir of unabsorbed sulphetrone in the gut (Brownlee et al. 1948). Stasis is therefore always to be guarded against. Another risk, exemplified in the present series, is tuberculous ulceration of the gut, leading to immediate increased absorption of sulphetrone.

TABLE I—SUMMARISED RESULTS OF SULPHETRONE THERAPY IN TUBERCULOSIS

It has been convenient to summarise the systematic management of sulphetrone patients in the form of a special chemotherapy chart devised by Anderson and Strachan (1948), which, besides the temperature, pulse, respiration, and weight, shows the intake of sulphetrone and the blood-sulphetrone level, fluid intake and output, blood-picture, hæmoglobin concentration, erythrocyte-sedimentation rate (E.S.R.), and the bacteriological findings.

MATERIAL

Sulphetrone therapy was investigated in the following groups: (1) early, purely exudative, limited pulmonary lesions, where collapse therapy was not considered essential; (2) chronic bilateral hæmatogenous pulmonary lesions; (3) unilateral fibrocaseous disease, to prevent local or contralateral exudative spread and render surgical intervention less hazardous; (4) extensive bilateral disease, to make the patient fit for surgery; and (5) outpatients whose condition had not materially improved after one or more periods of sanatorium treatment. Of the outpatients, 8 had progressive bilateral fibrocaseous disease of an extent which contra-indicated surgical intervention, 2 had chronic bilateral hæmatogenous pulmonary foci, 3 had productive infiltration, and 3 had essentially exudative pulmonary lesions. No special restrictions were imposed on these outpat so that, should improvement result the analysis wo not be complicated by ancillary therapy.

RESULTS

Table I summarises the results in 70 cases. For co venience the grouping is based on a descriptive ra than a pathological classification. The therape assessment of sulphetrone is based on changes in weig E.S.R., and bacteriology of sputum; clinical and ra logical improvement; and achievement of the spec target, a point on which particular emphasis is l Table II gives additional details showing typical respo to sulphetrone in 25 cases.

Group I: Meningitis.—In 3 cases of proved tubercu meningitis in a late stage no benefit was derived from sulph trone; 1 case of miliary tuberculosis of lungs progressed t tuberculous meningitis. The fifth patient presented w chronic miliary tuberculosis. The miliary pattern resolv after thirteen weeks of streptomycin therapy, but four wee later there was a vicious flare-up in the left hilar glands, w much constitutional disturbance and a rise in E.S.R. fr *18 to 52 mm.* (Westergren). This acute exacerbation cau anxiety in view of our experience of the establishment o *streptomycin-resistant strains in other cases* (Madigan et a 1947), sulphetrone was exhibited in adequate dosage, and two months later the hilar glandular enlargement had subsid

TABLE II—*continued*

Sex and age (yr.)	Clinical history	Total dose (g.)	Days	Av. blood-sulphetrone level (mg. per 100 ml.)	Weight	E.S.R. (mm. in 1st av.)	Sputum	Summary	Results
F 18	Acute bilateral fibrocaseous disease upper lobes. Tuberculous bronchopneumonia lower lobes. Small cavity rt. upper lobe. Large cavity lt. upper lobe. Much constitutional disturbance	2590	370	8–10	Gain 1 st. 5 lb.	60/22 (W)	+/+	Prognosis very grave, but infiltration markedly regressed; cavities smaller, original bronchopneumonic foci now calcified. Radiogram (Jan., 1948) shows fibrocalcareous disease; small thin-walled cavity lt. upper lobe	Much improved
M 16	Very bad family history. Radiogram (Oct., 1944) showed acute fibrocaseous disease rt. upper ²/₃. Exudative infiltration lt. lung spread considerably in 2 weeks. Grave constitutional disturbance. Too ill for active treatment	641	130	5–8	Gain 1 st. 3 lb.	21/8 (C)	+/−	After 1 mo. on sulphetrone infiltration of lt. lung reduced. After 4 mos. on drug reduction of bilateral infiltration such that rt. A.P. possible with less risk of complication	Improved
M 20	Acute bilateral fibrocaseous disease. 18 mos. in san. but continued to deteriorate. Rt. A.P. complicated by mixed empyema and bronchopleural and cutaneous fistulæ. Taken from san. moribund. Treated with sulphetrone at home	750	150	4–6	Stationary	..	+/+	After 1 mo. on sulphetrone appeared less toxic; no effect on empyema, but bronchopneumonic disease lt. 1, 2 improved. A month after withdrawal of drug patient died	Died
F 18	Radiogram (Nov. 18, 1943) showed acute fibrocaseous disease lt. 1, 2; large cavity lt. upper lobe; some infiltration rt. lower lobe. Much constitutional disturbance. Unsuitable for lt. A.P.	†	†	5–7	Loss 4 lb.	21/18 (C)	+/+	After first 6 mos.' course much reduction of infiltration. At end of 2nd course in san. began to deteriorate; discharged. 3rd course given in hosp. with P.P. Improved again and fit for lt. thoracoplasty; four-stage op. performed Autumn, 1947	Improved
F 28	Very toxic; radiogram (Aug. 24, 1943) showed acute fibrocaseous disease rt. upper lobe; patchy exudation lt. middle ¹/₃. Too toxic for active treatment	700	152	6	Gain 15 lb.	22/10 (C)	+/−	Rt. A.P. risked 2 mos. after sulphetrone; abandoned owing to massive effusion after attempted section of adhesions. Effusion remained sterile; sputum became neg. Very well Feb., 1948; no thoracoplasty necessary	Much improved
F 32	Bilateral pulmonary tuberculosis for 9 yr. In hospital since Sept. 2, 1946. General deterioration. Tuberculous larynx. Radiogram showed bilateral fibrocaseous disease	394	146	1	Not weighed	28/28 (W)	+/+	Too toxic for adequate daily dosage. Deterioration not halted	Died
M 13	Radiogram (June 1, 1946) showed bilateral chronic fibrocaseous disease all lobes. Little gained by san. and P.P. Sulphetrone given as O.P. from June 25, 1947	750	248	1–5	Gain 3 lb.	120/90 (W)	+/−	Infiltration decreasing; replacement fibrosis; focal calcification more clearly defined; cavities still open	Slightly improved
M 27	Diagnosed 1941. Radiogram showed extensive fibrocaseous disease rt. 1, 2, 3. Two san. periods. Serial radiograms 1947, both lungs heavily involved; huge cavity rt. upper lobe; small cavity 3rd lt. interspace. In hospital Oct. 17, 1947. Sulphetrone objective: clear infiltration and make fit for rt. thoracoplasty	670	100	7–11	Gain	30/5 (W)	+/+	Definite clearing of bilateral exudation. Cavity rt. upper lobe smaller. Almost ready for thoracoplasty	Improved
M 49	Chronic bilateral fibrocaseous disease; radiogram (Oct. 9, 1947) showed rt. upper ¹/₃ infiltrated, with cavitation; lt. upper lobe productive infiltration. Unsuitable for minor active measures. Sulphetrone objective: make fit for rt. thoracoplasty	605	108	6–7·5	Gain	13/3 (W)	+/−	Much clearing of exudative lesions. Ready for rt. thoracoplasty	Improved
M 39	Neglected hæmoptyses 1945 and June, 1946. Radiogram showed bilateral chronic fibrocaseous disease of rt. upper lobe with cavitation; rest of both lungs infiltrated. Tuberculous laryngitis. Ischiorectal abscess, with spread of ulceration to perianal region and most of left buttock. Condition serious	1052	223	8	Gain	85/2 (W)	+/−	Larynx improved. Infiltration in both lungs much reduced. No cavitation now in rt. upper lobe. Lt. lung quiescent. Ready for rt. thoracoplasty. Ischiorectal abscess and buttock ulceration healed	Much improved
M 38	Chronic bilateral fibrocaseous disease 6 yr. Radiogram (April 29, 1945) showed productive infiltration creeping towards bases; sulphetrone in O.P. to arrest spread	1133	329	2–5	Gain	13/11 (C)	+/+	Infiltration in both lungs reduced. Basal spread halted but cavities not closed	Improved
F 28	In hospital April 22, 1946. Grave constitutional disturbance. Radiogram showed moderate rt. pleural effusion and patchy tuberculous bronchopneumonia both lungs	727	178	5	Gain	15/4 (C)	+/−	Sulphetrone reduced patchy infiltration	Improved
M 18	In hospital Feb. 12, 1943. Grave constitutional disturbance. Very large peritoneal effusion. Large rt. pleural effusion. Cardiovascular and renal tract normal. Opinions favoured tuberculosis	350	40	3–6	Gain	31/10 (W)	Nil	Favourable progress. Discharged July 1, 1943	Much improved
M 30	Pleural effusion 1927. Tuberculous rt. knee-joint 1928. Bilateral tuberculous kidneys 1944. Several periods in institution	.. ..	(i) 300 (ii) 90	2–3 2·5	Gain	0/4 (W)	+/±‡	Lt. nephrectomy July, 1947. Gross destructive lesions present	No change
M 19	In hospital Sept. 13, 1945. Recently healed lesion in vertebræ L2, L3; active and severe caries of D8–10. Large rt. paravertebral abscess. Large pure chylous pleural effusion. Moderate pericardial effusion. Poor general condition with constitutional disturbance for several mos. after admission	774	182	1–4	Gain	25/4 (C)	+/−	Sulphetrone, later combined with 3 mos. streptomycin, changed outlook. Temperature began to settle; E.S.R. quickly fell; patient, so long unresponsive, began to improve. Discharged with lesions quiescent. Now well	Much improved

* Gastric lavage negative. † Three interrupted courses of sulphetrone, each lasting 6 months, between December, 1943, and April, 1946.

)rganisms reduced from very many to very few. O.P. = Outpatient. A.P. = Artificial pneumothorax. P.P. = Pneumoperitoneum.

considerably, E.S.R. was 3 mm. (Westergren), with much general improvement, quiescence followed, and the patient was discharged in excellent condition twenty weeks later.

Group II : Primary Pulmonary Disease.—In 3 cases of mediastinal glands causing segmental or lobar collapse there was improvement without rapid re-expansion of atelectasis. A case of primary cavitation of the right lower lobe showed early resolution of surrounding infiltration, with cavity closure and sputum conversion.

Group III : Strictly Exudative Pulmonary Lesions.—Of 8 patients in this category 3 were outpatients; 7 improved, with decreased infiltration, fibrosed lesions, and earlier calcification than anticipated. Sputum conversion resulted in all cases (3) originally positive. Of 2 patients with fresh bilateral exudative infiltration superimposed on old fibrotic lesions 1 presented with an acute attack, with extensive parenchymatous exudation. In spite of a large series of positive sputa, twelve months' sulphetrone therapy (six as outpatient) cleared the infiltration completely, with sputum conversion which remains negative on culture during a two-year follow-up.

Group IV : Chronic Bilateral Pulmonary Hæmatogenous Disease.—Of 4 cases (2 in outpatients) definite clearing was observed in all. Recrudescence was observed in 3, from eighteen to twenty-four months after withdrawal of sulphetrone, and in 2 the condition is characterised by the appearance of a small apical cavity. Thus the pattern of the relapse conforms to fibrocaseous disease.

Group V : Strictly Productive Pulmonary Infiltration.—Of 4 cases treated as outpatients 3 improved. In the patient showing no change the blood-sulphetrone level did not exceed 1 mg. per 100 ml.

Group VI A : Acute Pulmonary Fibrocaseous Disease.—Six patients who were gravely ill presented with acute bilateral fibrocaseous disease complicated by a progressive tuberculous bronchopneumonia. In all of them the additional load on an already taxed resistance warranted a very bad prognosis. In 2 patients the extensive infiltrative processes gradually but completely resolved, and in 1 the bronchopneumonic foci completely calcified. The soft extensive lesions of a third patient hardened, and the final radiological picture was that of chronic fibrocaseous disease. So seriously ill and with so extensive an involvement of both lungs were the 3 remaining patients that the immediate prognosis was grave and benefit from sulphetrone was not to be expected.

Five seriously ill patients presented with acute unilateral fibrocaseous disease and rapidly progressive contralateral exudative infiltration. In 2 of them this latter condition had developed within three weeks. In all 5 cases the extent of the disease, the acuteness of the condition, and the toxicity of the patient strongly contra-indicated immediate surgical intervention. Without exception the exudative process was not only halted but also began to regress as soon as sulphetrone therapy was established. In 3 cases collapse of the more affected lung became possible with ultimate control of the lesion, no intervention being necessary on the other side.

Three severely ill patients presented with acute unilateral fibrocaseous disease without evidence of contralateral involvement. One of these, who died before a therapeutic blood-sulphetrone level was reached, is discussed below. The second improved considerably. The third, a repatriated prisoner-of-war who experienced the Thailand railway ordeal, was very ill on admission. Sulphetrone controlled his toxic manifestations. After a combined second course of sulphetrone and streptomycin a change from acute to chronic disease ensued. Numerous negative sputum cultures were obtained, there was radiological evidence that the cavity had closed, and quiescence was presumed. Four months after his discharge the cavity had reopened and his sputum again contained tubercle bacilli. Control was regained by performing an artificial pneumothorax.

Group VI B : Chronic Pulmonary Fibrocaseous Disease.—Of 20 patients, improvement was recorded in 13, of whom 8 were outpatients.

One man, aged 39, had chronic fibrocaseous disease of the right lung, productive infiltration in the upper half of the left lung, early tuberculosis of the larynx, and an ischiorectal abscess complicated by gross perianal ulceration with extension to most of the left buttock. The prognosis was bad. Sulphetrone therapy led to healing of the perianal ulceration and ischiorectal abscess. The sputum became negative on culture, and the E.S.R. fell from 85 to 2 mm. (Westergren). There was much clearing of tuberculous infiltration and reduction of the cavity in the right lung; and the disease became quiescent in the left lung. The larynx practically healed and the patient was fit to undergo a right-sided two-stage thoracoplasty.

Another patient had had bilateral pulmonary tuberculosis since 1941. All the lobes of the right lung were infiltrated and there was a massive apical cavity. Both lobes of the left lung were infiltrated, and there was a small cavity at the level of the third interspace. There was well-marked clearing of the bilateral exudative infiltration in ten weeks, the apical cavity was reduced in size, and the E.S.R. fell from 30 to 5 mm. The patient was fit to undergo right thoracoplasty three months after the start of sulphetrone therapy.

A third patient was a man, aged 49, with bilateral fibrocaseous tuberculosis of the upper lobes and cavitation of the right apex. After four months' sulphetrone therapy the infiltration was clearing and the left apical disease was controlled. The patient underwent a successful right-sided thoracoplasty on July 7, 1948.

A fourth patient was a man, aged 28, with a cavity in the right upper lobe, hæmoptysis, and an extensive bronchogenic spread to all lobes of both lungs. After the induction of an artificial pneumoperitoneum on May 22, 1947, the lesion became slightly smaller, but the exhibition of sulphetrone, begun on Oct. 1, brought about definite clearing of the patchy infiltration.

A fifth patient was a man, aged 38, with bilateral chronic fibrocaseous pulmonary tuberculosis since 1940, which had begun to spread to the bases in 1945. Sulphetrone was prescribed for him as an outpatient for 329 days. The basal extension stopped and hardened, and infiltration in both lungs was much reduced.

Of the 7 patients who did not respond 3 had very advanced disease, in a fourth patient a resistant strain of tubercle bacilli had developed after the use of streptomycin, and the 3 others were outpatients whose blood-sulphetrone was not raised to the optimal therapeutic level owing to their poor nutrition.

Group VII : Bronchopneumonic.—One improved case is reported in table II; the second was one of bilateral bronchopneumonia in a woman, aged 29, whose condition remained unchanged after a six-month course of sulphetrone.

Group VIII : Serous Effusion.—A boy, aged 13, had been ill for three weeks before admission on Feb. 15, 1943. Gross constitutional disturbance; temperature 100–104°F, large right pleural and peritoneal effusions, which were clear, predominantly lymphocytic, and sterile. Mantoux test positive. No organisms isolated, but a consensus of several opinions favoured a diagnosis of tuberculosis. The patient made good progress and was discharged in good condition on July 1, 1943.

Group IX : Urogenital.—In one uncomplicated case tubercle bacilli were isolated from both kidneys by ureteric catheterisation. Intravenous pyelography indicated marked damage in the left kidney. Two courses of sulphetrone were given. The number of organisms was much reduced during the first course. Later radiograms showed calcification of the left kidney. The patient underwent left nephrectomy in July, 1947, and is now well. The second patient had tuberculosis of the upper pole of the left epididymis. The swelling continued to enlarge but slowly subsided after three months' sulphetrone therapy. This patient also had fibrocaseous pulmonary tuberculosis.

Group X : Skeletal.—The single case had recently healed caries of L2 and L3 and gross caries of D8–10, a large paravertebral abscess, and an effusion of pure chyle in the right pleural cavity. The condition had been static for a long time before sulphetrone was given. The first achievement was the reduction of the E.S.R., which had been high for months. Reduction of the paravertebral abscess, bony regeneration in rarefied vertebræ, and general improvement followed in due course. The patient remains well fifteen months after discharge.

TOXICITY

The part played by iron and yeast in treating anæmia of diverse origin caused by sulphetrone and the fact that polyneuritis is avoided by the administration of yeast ve already been mentioned. A residual effect is a emolytic anæmia due to sulphetrone, and a compen- tory reticulocytosis of as much as 10% may be present Brownlee 1948).

Minor inconvenience due to the physiological adjust- ent which the increase in alkali reserve calls forth is served during the first three weeks while blood- lphetrone levels are being built up, and it has been ted that the bicarbonate ion provides relief.

Major intoxication is observed when blood-sulphetrone vels in excess of 12·5 mg. per 100 ml. are allowed to rsist for several days. The onset of symptoms appears be related to the patient's nutrition, and in particular the reserves of B-complex vitamins. The ultimate hology is anoxia, first reflected in a diminished acity of the red cells to transport oxygen; the mical state of the hæmoglobin may or may not be ected, and methæmoglobinæmia is not a constant ture, being observed only terminally. This insidious icity was observed in 1 patient with extensive lateral fibrocaseous disease, of low vital capacity, l acutely ill, before the therapeutic value of yeast l been appreciated. Constipation for several days owed a reservoir of unabsorbed sulphetrone to accumu- e in a static gut, with the result that a blood-sulphe- ne level of 17·5–20 mg. per 100 ml. was maintained about six days with fatal consequences.

Sulphetrone has no toxic effect on white cells or their duction. In the only instance observed, granulo- topenia responded to folic acid; it recurred on administration of sulphetrone and again responded to lic acid. Sulphetrone was then discontinued. The ficiency state in this case was considered to be of tritional origin.

Abnormal Blood Pigments.—So rarely were these countered, though systematically sought, that for actical purposes they are not rated as a risk. They have en described by Brownlee (1948).

DISCUSSION

The difficulty of assessing the results of chemotherapy tuberculosis, due to its unpredictable course and to the hical considerations already mentioned, has not been solved in the present series of 70 observations spread ver five years.

Various periods of continuous sulphetrone therapy are cluded in the present series; from three to six months common, and from six to nine months usual. Several atients had continuous sulphetrone therapy for twelve onths, and 2, with average blood-sulphetrone levels of mg. per 100 ml., for eighteen months. The simultaneous xhibition of iron and yeast prevented the onset of næmia of hypochromic and nutritional origin.

It is in the cases which improved that difficulty of terpretation arises. Included in assessment are all vailable data, such as changes in E.S.R., sputum con- ersion, other relevant bacteriology, and changes in eneral health and in weight, together with the radio- gical evidence. As a general overriding consideration here is the question of whether the target set was reached. n allocating credit there is the need, on the negative de, to discount the positive effects of ancillary hospital herapy, and, on the positive side, for conservative linical judgment because of the variation in the expected athological picture induced by chemotherapy.

In general, sulphetrone therapy effectively combated filtrative exudative lesions wherever these were bserved. The radiological changes were accompanied y improvement of general condition, control of fever, nd reduced E.S.R. Falls in E.S.R. are characteristically recipitous; so much so that alternative explanations ave been sought but not found. Improvements in xudative disease have been greatest in pulmonary fibrocaseous disease, a fact which I have associated with evidence of host-resistance. The capacity of chemo- therapy to resolve infiltration of this kind had so impressed me by the second phase of the trial that it gave rise to the conception of "objectives" or "targets" in an adjuvant sense. It is in this capacity that sulphone therapy seems likely to be most useful.

The protracted nature of chemotherapy of tuberculosis should be emphasised, periods of observation being measured in units of three months. The necessity for a scheme of management and for laboratory control has already been mentioned. Provided blood-sulphetrone levels above 10 mg. per 100 ml. are not exceeded, only minor toxic signs will be met. Should blood-sulphetrone levels above 12·5 mg. be persisted in, major disasters can confidently be predicted. Nevertheless sulphetrone therapy of tuberculosis can play a useful part, as a well-defined adjuvant measure, in the control of exudative tuberculosis.

SUMMARY

In 70 cases of tuberculosis affecting different organs sulphetrone was given for periods which varied from a few days in tuberculous meningitis to eighteen months in more chronic cases.

Whether sulphetrone is given parenterally or by mouth, a gradual increase of dosage is necessary to build up therapeutic blood-sulphetrone levels of 7·5–10 mg. per 100 ml. if toxic symptoms are to be avoided.

It is also essential to give iron and brewers' yeast to avoid hypochromic and nutritional anæmia. Even so a residual hæmolytic anæmia will arise, leading to a fall in hæmoglobin concentration though not to below 60% (Haldane).

To avoid major toxic emergencies, seen when blood-sulphetrone levels above 12·5 mg. per 100 ml. are allowed to persist, a scheme of management is suggested.

In general no beneficial effect was detected from sulphetrone therapy of acute infections—e.g., acute miliary tuberculosis and tuberculous meningitis—but a patient with chronic miliary tuberculosis recovered. On the other hand, improvement was observed in chronic lesions. Thus 12 out of 17 cases of acute pulmonary fibrocaseous disease, and 13 out of 22 chronic cases, improved. All of 4 cases of primary pulmonary tuberculosis, and 6 out of 8 strictly exudative lesions, improved. In the chronic hæmatogenous group all of 4 cases improved, and in the productive pulmonary infiltrative group 3 out of 4 improved.

In general, all exudative phases of infiltrative disease were halted and reversed by sulphetrone.

The need for long-continued courses is emphasised, units of observation being three months, and routine laboratory control is essential.

Sulphetrone is useful as an adjuvant with definite objectives in view.

I wish to thank the Wellcome Foundation Ltd. for supplying sulphetrone; the Wellcome Physiological Research Laboratories, Beckenham, for establishing close laboratory liaison through Dr. G. Brownlee, and for giving unlimited aid at all times; the hospital pathological laboratory for coöperation of the highest order; Dr. J. F. Hackwood, medical superintendent, for encouragement; and the nurses under Sister Clancy, without whom the trial could not have been carried through.

In 70 cases of tuberculosis affecting different organs sulphetrone was given for periods which varied from a few days in tuberculous meningitis to eighteen months in more chronic cases.

Whether sulphetrone is given parenterally or by mouth, a gradual increase of dosage is necessary to build up therapeutic blood-sulphetrone levels of 7·5–10 mg. per 100 ml. if toxic symptoms are to be avoided.

It is also essential to give iron and brewers' yeast to avoid hypochromic and nutritional anæmia. Even so a residual hæmolytic anæmia will arise, leading to a fall in hæmoglobin concentration though not to below 60% (Haldane).

To avoid major toxic emergencies, seen when blood-sulphetrone levels above 12·5 mg. per 100 ml. are allowed to persist, a scheme of management is suggested.

In general no beneficial effect was detected from sulphetrone therapy of acute infections—e.g., acute miliary tuberculosis and tuberculous meningitis—but a patient with chronic miliary tuberculosis recovered. On the other hand, improvement was observed in chronic lesions. Thus 12 out of 17 cases of acute pulmonary fibrocaseous disease, and 13 out of 22 chronic cases, improved. All of 4 cases of primary pulmonary tuberculosis, and 6 out of 8 strictly exudative lesions, improved. In the chronic hæmatogenous group all of 4 cases improved, and in the productive pulmonary infiltrative group 3 out of 4 improved.

In general, all exudative phases of infiltrative disease were halted and reversed by sulphetrone.

The need for long-continued courses is emphasised, units of observation being three months, and routine laboratory control is essential.

Sulphetrone is useful as an adjuvant with definite objectives in view.

I wish to thank the Wellcome Foundation Ltd. for supplying sulphetrone; the Wellcome Physiological Research Laboratories, Beckenham, for establishing close laboratory liaison through Dr. G. Brownlee, and for giving unlimited aid at all times; the hospital pathological laboratory for coöperation of the highest order; Dr. J. F. Hackwood, medical superintendent, for encouragement; and the nurses under Sister Clancy, without whom the trial could not have been carried through.

a day, provided that facilities are available for the estimation of blood-sulphetrone levels, hæmoglobin percentage, and red-cell and white-cell counts. The blood-level should not exceed 12 mg. per 100 ml. Iron and yeast should also be given to prevent a fall in the hæmoglobin level.

Further trials with sulphetrone in selected cases are warranted.

SUMMARY

Sulphetrone was given to 57 patients with tuberculosis. Only 44 of these cases, 42 of which were pulmonary, were treated long enough for the results to be assessed.

Improvement was noted in 22, 5 were unchanged, 6 became worse, and 11 died. Of those who improved, 9 improved considerably, 7 moderately, and 6 slightly. Improvement was not dramatic, and at best sulphetrone can only be regarded as an adjuvant and not in any way as a specific for tuberculosis.

Sulphetrone produced toxic side-effects (nausea, vomiting, anorexia, headache, depression, drug rash, and disturbances of vision) in 6 out of 57 patients. These effects disappeared on the withdrawal of the drug.

Sulphetrone lowers the hæmoglobin level, but this can be corrected by iron and yeast.

Sulphetrone should be used only if there are facilities for estimating blood-sulphetrone levels and for carrying out blood-counts.

Further trials with sulphetrone in selected cases are warranted.

We wish to thank Dr. F. Prescott of the Wellcome Foundation, who kindly supplied the sulphetrone; and Dr. John Smith, director of the City Hospital laboratory, for his interest and coöperation in this investigation.

RADICAL CURE OF INGUINAL HERNIA WITH A PLASTIC INSERT

WALTER THOMPSON
M.B. Leeds, F.R.C.S.
RESIDENT SURGICAL OFFICER, MANCHESTER ROYAL INFIRMARY

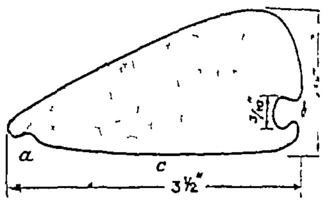
IN 1909 McGavin published his operation for the cure of inguinal hernia with double filigree inserts, and the operation was reviewed by Cole (1941). The attention of surgeons was directed to the excellent results. This paper is intended to introduce a new operation using plastic material instead of the silver filigree wires, and the operation is based on McGavin's.

Messrs. Portland Plastics Ltd., of London, kindly supplied me with plastic sheeting $^1/_{16}$ *in. thick made of poly-ethylene—formula* CH_2 (*n* times). This material was thought, from its chemical composition, to be completely inert in the body. Only small amounts of plasticisers are used in its manufacture. It can be produced in various grades of hardness, depending on the degree of polymerisation. Grade 200 was chosen, since it is flexible and can be easily cut with scissors, yet is firm enough, when $^1/_{16}$ in. thick, to withstand the normal muscular strains of the body without bending. *Poly-ethylene can also be easily sterilised by boiling.*

OPERATION

The routine inguinal incision is used; and, after division of the external oblique aponeurosis, the cord, conjoint tendon, and iliohypogastric and ilio-inguinal nerves are defined. The cremaster muscle, along with the inguinal nerve, both in front and behind the cord, is separated and removed. The cremasteric vessels are ligated and divided at their origin from the deep epigastric vessels. The sac is then dissected free and dealt with in the usual manner.

The transversalis fascia is next incised below the arching fibres of the transversalis muscle and the conjoint tendon, exposing the extraperitoneal fat. The peritoneum is then dissected clear from the poster aspect of the muscles of the abdominal wall, upwa inwards, and outwards for $1^1/_2$ in. This is an essen step of the operation and provides the bed in which the plastic insert lies. It is usually not necessary to div the deep epigastric vessels, for these can be carried w *the peritoneum* away from the abdominal musculature.



Poly-ethylene insert for inguinal hernia: notch for pubic spine; (b) notch for sper matic cord and vessels; (c) slightly curv lower border.

The poly-ethylene sheeting is next taken from the steriliser and cut with scissors to fit in the bed so formed. The size and shape in an average case are as in the accompanying figure. The edges are bevelled with an scalpel before insertion. The vas and vessels will ha previously been dissected free from the floor of the iliac fossa and from the neck of the sac when the latter structure was dissected free. The vas and vesse are now placed in the niche provided in the plastic insert and this is slipped in a lateral direction *under the free* arching fibres of the internal oblique and transversalis muscles. The lower edge comes to lie along Poupart's ligament, and the medial acute angle is pushed behind the insertion of the rectus abdominis muscles into the pubic spine.

A medium-sized nylon suture is then taken, and the lower edge *of the plastic insert* is perforated with Mayo's needle and stitched with interrupted sut to Poupart's ligament. The first essential stitch is one which perforates the plastic sheeting at its angle and encircles Poupart's ligament as it is in into the pubic spine. The other essential stitch fix the edge of the plastic sheeting to Poupart's ligam *opposite the origin of the fibres of the internal obli* muscle.

The cord lies in front of the plastic sheet; the internal ring and the deep epigastric vessels, the ext peritoneal fat, and the peritoneum, and the lower fi of the transversalis fascia come to lie behind the pla insert. The new internal ring is thus displaced outwar and upwards 1 in. and comes to lie directly behind the strong arching fibres of the transversalis and inter oblique muscles. The conjoint tendon is next sutu to Poupart's ligament in front of the plastic sheet and behind the cord by a running catgut stitch. T external oblique and the skin are sutured in the ortho manner.

ANÆSTHESIA AND POSTOPERATIVE TREATMENT

The routine form of anæsthesia used is 'Spin Amethocaine' 1%, dextrose 6·3% (Duncan, Flockhart Co.) and has been found to be very satisfactory, spinal headaches have ensued. Local anæsthes been used on four patients, owing to their condition; two of them were over 80 years of age.

The patient is instructed in breathing exer immediately on return to the ward, and next day takes part in the routine ward exercises. These gradually increased in range, and he is allowed up the ninth day. Owing to pressure on beds patients been discharged home on the tenth postoperative by ambulance. They are instructed to get up increasing periods during the next fortnight. The patients have been got up on the second day, and period has been gradually increased day by day they are up and dressed for most of the day by the postoperative day.

INDICATIONS AND RESULTS

atients have been chosen for this operation who ld normally have had a fascial graft. The youngest aged 35 years and the oldest 84.

iis operation has been performed on more than ity patients since August, 1946. All the wounds ed by first intention except in one patient who loped a subcutaneous hæmatoma, which required ation. One patient required a course of penicillin sulphamezathine for a moderately serious chest ition. These patients have been carefully watched h by month at the routine follow-up clinic. No rences have been observed, and there appears to ery little fibrous-tissue reaction round the plates, h can be palpated easily. The patients seem to complained of less pain after this operation than a Gallic fascial graft. However, the intelligent say they can feel a resistance in the inguinal region ending to fasten their shoes. Plastic inserts have been used with success in umbilical herniæ.

SUMMARY

new method of curing inguinal hernia is described h is based on the filigree operation of McGavin 9). Plastic inserts of poly-ethylene are used instead lver filigree.

ie results in twenty cases are reviewed.

is work has been carried out under the direction of A. Graham Bryce, surgeon at the Manchester Royal mary, whom I would like to thank for his stimulation advice. Very satisfactory samples of 'Polythene' sheet were kindly supplied by Imperial Chemical Industries , to whom I am also grateful for chemical details.

HANDKERCHIEFS IN THE TRANSFER OF RESPIRATORY INFECTION

R. Dumbell J. E. Lovelock E J. Lowbury
M.B. Lpool Ph.D. Lond. M.A., B.M. Oxfd

om the M.R C. Common Cold and Air Hygiene Units,
Harvard Hospital, Salisbury

HE rôle of the handkerchief in the spread of upper iratory infections has probably had less attention i it deserves. Hare (1941) demonstrated hæmolytic ptococci in the handkerchiefs of carriers of these nisms as well as in the bedding and dust of their ns, and his observations were confirmed by Hamger et al. (1944). Nose-blowing as a means of aminating the hands and environment with hæmo- streptococci has been investigated by Hamburger Green (1946).

he handkerchief collects both nasal and oral secretions, droplets of the latter escape also during sneezing rdillon et al. 1941) and in coughing (Duguid 1946a b, Hare and Mackenzie 1946). It is possible that l secretions are distributed predominantly by the lkerchief, but for this to happen efficiently the lkerchief must be dry (Willits and Hare 1941).

iese and other observations suggested to us that an nate of the numbers of potentially infective particles ated by the shaking of dry handkerchiefs would a useful preliminary to a study of some of the ors concerned in the transfer of respiratory infection person to person. The actual mechanism operating ich disease has to be studied on its own merits, but possibilities inherent in different routes may be ged by the total numbers of particles which may be lved in each. The experiments reported in this er were made to determine the numbers of bacteria-carrying particles which could be shaken from used handkerchiefs, and the reaction of these particles to aerial disinfectants.

NUMBERS OF PARTICLES DETACHABLE FROM HANDKERCHIEFS BY SHAKING

Volunteers for the common cold research programme arrive at this unit at the rate of two dozen every second week, and careful records are kept of their nasal condition. Some develop colds during their stay and illustrate varying degrees and types of nasal secretion. For these reasons they formed an admirable population for the proposed handkerchief study.

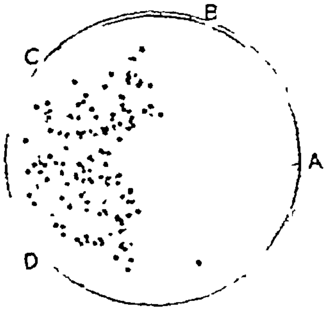

Fig. 1—A typical slit-sampler plate from a $^{1}/_{2}$ min. shaking of a used handkerchief. A, B, C, D, mark first three $^{1}/_{2}$ min. sectors of plate. AB is the background sector. Shaking began at B and continued till C. Sectors AB and CD were counted, and count of particles shaken from the handkerchief was found by subtracting AB from CD.

Method

Our handkerchiefs were of Egyptian cotton parachute material and were about 1 ft. square. They were issued sterile to volunteers and collected again after two days' use. They were allowed to dry overnight at 70°F in a quiet dust-free room, and next day were shaken one at a time by being held in the air stream of a $^{1}/_{2}$ h.p. blower. The shaking was done in a small airtight room of 400 cu. ft. capacity, with walls of washable concrete. The floor was kept wet with calcium chloride solution to prevent raising of dust by the air stream of the blower. The room was so arranged that, after the handkerchief had been fixed in front of the blower, all subsequent operations could be controlled from outside. A more detailed description of this room will be given in a subsequent paper.

The suspended particles were sampled immediately by a slit sampler (Bourdillon et al. 1941) on to nutrient agar plates enriched by 5% of horse serum. The routine procedure was first to fix the handkerchief in front of the blower. The room was then ventilated by an exhaust fan for 2 min., which sufficed for twenty air changes. After this the room was closed and a 2 cu. ft. sample of air taken over a period of 2 min. For the first $^{1}/_{2}$ min. the "background" air alone was sampled; then, during the whole of the second $^{1}/_{2}$ min., the blower was switched on and the handkerchief was violently shaken. Sampling was continued for the full minute after this. Plates were incubated for 24 hours at 37°C and colony counts made on the $^{1}/_{2}$ min. background sector (fig. 1) and the $^{1}/_{2}$ min. sector immediately following the cessation of shaking.

Filtered air was blown into the room, creating a slight positive pressure which prevented any leakage of external air into the room during the experiment. Serum-agar plates were also exposed at different sites within the room to collect samples of particles large enough to settle almost immediately, but the slit sampler collected efficiently particles of all sizes which would remain airborne during the experiment.

Results

A series of tests was made to determine the efficiency of the shaking technique. In these, handkerchiefs were shaken for 6 min. with continuous sampling. Counts on these showed that about half the total number of particles removable by shaking were extracted in the first $^{1}/_{2}$ min.

a day, provided that facilities are available for the estimation of blood-sulphetrone levels, hæmoglobin percentage, and red-cell and white-cell counts. The blood-level should not exceed 12 mg. per 100 ml. Iron and yeast should also be given to prevent a fall in the hæmoglobin level.

Further trials with sulphetrone in selected cases are warranted.

SUMMARY

Sulphetrone was given to 57 patients with tuberculosis. Only 44 of these cases, 42 of which were pulmonary, were treated long enough for the results to be assessed.

Improvement was noted in 22, 5 were unchanged, 6 became worse, and 11 died. Of those who improved, 9 improved considerably, 7 moderately, and 6 slightly. Improvement was not dramatic, and at best sulphetrone can only be regarded as an adjuvant and not in any way as a specific for tuberculosis.

Sulphetrone produced toxic side-effects (nausea, vomiting, anorexia, headache, depression, drug rash, and disturbances of vision) in 6 out of 57 patients. These effects disappeared on the withdrawal of the drug.

Sulphetrone lowers the hæmoglobin level, but this can be corrected by iron and yeast.

Sulphetrone should be used only if there are facilities for estimating blood-sulphetrone levels and for carrying out blood-counts.

Further trials with sulphetrone in selected cases are warranted.

We wish to thank Dr. F. Prescott of the Wellcome Foundation, who kindly supplied the sulphetrone; and Dr. John Smith, director of the City Hospital laboratory, for his interest and coöperation in this investigation.

RADICAL CURE OF INGUINAL HERNIA WITH A PLASTIC INSERT

WALTER THOMPSON
M.B. Leeds, F.R.C.S.
RESIDENT SURGICAL OFFICER, MANCHESTER ROYAL INFIRMARY

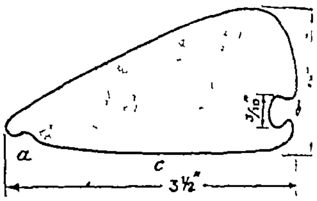
IN 1909 McGavin published his operation for the cure of inguinal hernia with double filigree inserts, and the operation was reviewed by Cole (1941). The attention of surgeons was directed to the excellent results. This paper is intended to introduce a new operation using plastic material instead of the silver filigree wires, and the operation is based on McGavin's.

Messrs. Portland Plastics Ltd., of London, kindly supplied me with plastic sheeting $^1/_{16}$ in. thick made of poly-ethylene—formula CH_2 (n times). This material was thought, from its chemical composition, to be completely inert in the body. Only small amounts of plasticisers are used in its manufacture. It can be produced in various grades of hardness, depending on the degree of polymerisation. Grade 200 was chosen, since it is flexible and can be easily cut with scissors, yet is firm enough, when $^1/_{16}$ in. thick, to withstand the normal muscular strains of the body without bending. Poly-ethylene can also be easily sterilised by boiling.

OPERATION

The routine inguinal incision is used; and, after division of the external oblique aponeurosis, the cord, conjoint tendon, and iliohypogastric and ilio-inguinal nerves are defined. The cremaster muscle, along with the inguinal nerve, both in front and behind the cord, is separated and removed. The cremasteric vessels are ligated and divided at their origin from the deep epigastric vessels. The sac is then dissected free and dealt with in the usual manner.

The transversalis fascia is next incised below the arching fibres of the transversalis muscle and the conjoint tendon, exposing the extraperitoneal fat. T peritoneum is then dissected clear from the poste aspect of the muscles of the abdominal wall, upwa inwards, and outwards for $1^1/_2$ in. This is an esse step of the operation and provides the bed in which plastic insert lies. It is usually not necessary to di the deep epigastric vessels, for these can be carried the peritoneum away from the abdominal musculature.



Poly-ethylene insert for inguinal hernia (notch for pubic spine; (b) notch for sp matic cord and vessels; (c) slightly cur lower border.

The poly-ethylene sheeting is next taken from the steriliser and cut with scissors to fit in the bed so formed. The size and shape in an average case are as in the accompanying figure. The edges are bevelled with an scalpel before insertion. The vas and vessels will ha previously been dissected free from the floor of th iliac fossa and from the neck of the sac when th latter structure was dissected free. The vas and vess are now placed in the niche provided in the plastic insert and this is slipped in a lateral direction under the free arching fibres of the internal oblique and transversalis muscles. The lower edge comes to lie along Poupart's ligament, and the medial acute angle is pushed behind the insertion of the rectus abdominis muscles into th pubic spine.

A medium-sized nylon suture is then taken, and th lower edge of the plastic insert is perforated wit Mayo's needle and stitched with interrupted st to Poupart's ligament. The first essential stitch is one which perforates the plastic sheeting at its angle and encircles Poupart's ligament as it is in into the pubic spine. The other essential stitch the edge of the plastic sheeting to Poupart's liga opposite the origin of the fibres of the internal obl muscle.

The cord lies in front of the plastic sheet; the internal ring and the deep epigastric vessels, the ext peritoneal fat, and the peritoneum, and the lower of the transversalis fascia come to lie behind the pl insert. The new internal ring is thus displaced outw and upwards 1 in. and comes to lie directly behind th strong arching fibres of the transversalis and inter oblique muscles. The conjoint tendon is next sutu to Poupart's ligament in front of the plastic sheet and behind the cord by a running catgut stitch. T external oblique and the skin are sutured in the ortho manner.

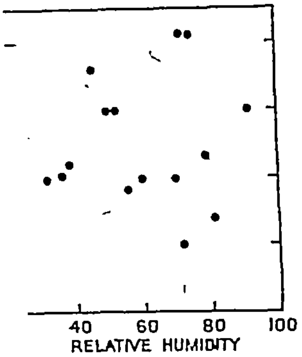
ANÆSTHESIA AND POSTOPERATIVE TREATMEN

The routine form of anæsthesia used is 'Spi Amethocaine' 1%, dextrose 6·3% (Duncan, Flock Co.) and has been found to be very satisfactory spinal headaches have ensued. Local anæsthe been used on four patients, owing to their g condition; two of them were over 80 years of age.

The patient is instructed in breathing ex immediately on return to the ward, and next day takes part in the routine ward exercises. These gradually increased in range, and he is allowed up the ninth day. Owing to pressure on beds patients h been discharged home on the tenth postoperative by ambulance. They are instructed to get up increasing periods during the next fortnight. The patients have been got up on the second day, and period has been gradually increased day by day they are up and dressed for most of the day by the te postoperative day.

measured natural die-away rates, and the values ie killing-rates due to the disinfectants were by subtracting the average settling-rate from lie-away rates measured in the presence of the ectants.

. 3 illustrates the distribution of settling-rates at dif- relative humidities. These settling-rates range from 21 per hour, and show little or no correlation with relative humidity. The average settling-rate is 12·5 per hour. Assuming the particles to be equivalent to spheres of density 1, this corresponds to a particle-size range of 12·5µ to 27µ in diameter and an average particle-size of 20µ in diameter. The comparison of counts on the settling plates with those taken in the slit sampler confirmed the estimates of size made from the die-away rates.



elationship between settling-rate ticles shaken from handkerchiefs lative humidity.

of Aerial Disinfectants

le II shows the results obtained with ultraviolet triethylene glycol, lactic acid, and α-hydroxy- ıyl-butyric acid at different relative humidities. disinfectants were chosen as being the most ve at present available.

three chemical disinfectants were liberated into r of the room by being dropped on to a hot plate ained at 200–250°C. This plate was placed just the air stream of a small table fan to ensure the mixing of the disinfectant vapour with the room he aerial concentration of each of the three chemical ectants used was about twice that recommended ıse in occupied rooms. Ultraviolet rays were ıed from a 100-watt quartz low-pressure mercury- ır lamp capable of an effect at least 100 times that in practical aerial disinfection. Even at the rable concentration levels of these experiments, l killing-rates were obtained only at lower relative dities with ultraviolet rays, and higher humidities lactic acid, than would normally be found in this try in winter. In view of the high settling-rate of particles (12·5 per hour) and the occurrence of lation-rates of at least 2·5 per hour in occupied s, a killing-rate of 15 per hour would be needed duce the count by half. In contrast, aerial dis- tants are rapidly and effectively bactericidal to rne particles expelled from the mouth in sneezing rdillon ét al. 1942).

E II—EFFECT OF AERIAL DISINFECTANTS ON HANDKERCHIEF PARTICLES

ıfectant gent	Killing-rate at relative humidity									Concentration of disinfectant (µg. per cu. ft. of air)
	10	20	30	40	50	60	70	80	90	
ıviolet s ..	40·5	..	25	18·5	10	10	10	..	..	*
hylene ıol ..	..	..	0	0	0	8	8	..	..	200
c acid..	..	..	0	0	10	37	82	75	60	150
droxy- nethyl- yric acid	..	..	0	0	2	15	15	2	..	200

, effective intensity of ultraviolet rays was about 100 times that ommonly used for aerial disinfection

DISCUSSION

The impressive fact that on the average 15,000, and occasionally as many as 50,000, particles may be distributed from a dry used handkerchief by gentle manipulation gains in significance when it is further realised that these particles while airborne are almost completely resistant to the action of the best available aerial disinfectants. Not only this, but they are eight times the weight of "droplet nuclei" from the mouth and may therefore carry a correspondingly larger content of micro-organisms. We believe these particles come chiefly from the nose, and Hamburger and Green (1946) have shown that streptococcal infections of the respiratory tract are spread very largely by the nasal carrier of that organism. Hare and Mackenzie (1946) suggest that this may well prove to be true in other specific infections. The relative numbers of particles and the total weights of dried secretion which they represent for the actions of coughing, sneezing, and gentle manipulation of the handkerchief were as follows:

	Sneezing (per sneeze)	*Coughing* (per cough)	*Handkerchief* (gentle waving for $^1/_2$ min.)
Av. no. of airborne particles ..	100,000 ..	400 ..	15,000
Size ..	10µ	.. about 10µ ..	20µ
Dried weight (g.) ..	10^{-4}	.. 4×10^{-7} ..	10^{-4}

Dried weight means weight of expelled airborne secretion in equilibrium with the relative humidity of the air. The numbers of airborne particles emitted during sneezing are quoted from Bourdillon et al. (1942), and during coughing from unpublished work of this unit.

Though the dried weights of material dispelled by sneezing and handkerchief waving are about the same, it is a matter of everyday observation that sneezing is much rarer than the using of the handkerchief. There are good reasons for believing that talking and nose blowing contribute few airborne particles, and therefore the use of the handkerchief is probably the most important single action, except bed making, in the contamination of the air with micro-organisms from the respiratory tract.

This paper is concerned entirely with the airborne particles coming from the shaking of handkerchiefs. It is fully realised that larger particles which settle rapidly, whether from coughing, nose blowing, sneezing, or handkerchief waving, may be of equal or greater importance in the spread of respiratory infection. This point is now being investigated.

SUMMARY

The number of bacteria-carrying particles which can be shaken from normally used handkerchiefs has been estimated.

The average number over a series of 211 handkerchiefs was 136,000.

These particles are resistant to the action of aerial disinfectants and ultraviolet rays at normal relative humidities.

Another series of tests was made to compare this standardised mechanical shaking with manual shaking performed by an operator wearing only bathing trunks and a dust mask, and with wet skin and hair, who remained inside the experimental room. The actions of a person using a handkerchief were imitated as closely as possible. The handkerchief was withdrawn from its pot, shaken to unfold, held near the nose, and replaced in the pot. This cycle of operations was repeated for $^1/_2$ min. (usually four times). The handkerchief was then shaken for $^1/_2$ min. by the routine technique.

Under these conditions roughly a fifth as many particles were removed by the gentle manual shaking as by vigorous mechanical agitation for the same period:

	Manual shaking		*Mechanical shaking*
	14,400	..	62,400
	22,000	..	55,200
	6000	..	42,000
	11,200	..	44,400
	33,200	..	100,800
	1600	..	20,400
	3200	..	23,200
	4400	..	29,200
	4000	..	30,200
	47,200	..	195,200
Total ..	147,200		603,000
Average ..	14,720		60,300
Ratio ..	1		4

The mechanical shaker thus gives an estimate of the total numbers of particles which can be shaken from a used handkerchief and has the advantage over manual shaking of a greater degree of reproducibility.

Even after shaking till no more particles were removed, as many again could be removed by extracting the handkerchief with 200 ml. of 10% broth-saline solution.

It is not maintained that all the bacteria-carrying particles shaken from the handkerchiefs came originally from the nose. A few plates showed many small colonies of non-hæmolytic streptococci similar to the mouth and throat flora, but in most of the plates examined most of the colonies were staphylococcal, resembling the flora of nose and skin. A large proportion of golden staphylococcal colonies was obtained from the handkerchiefs of most volunteers who showed an abundant growth of *Staph. aureus* from nose swabs.

Fig. 2 shows the distribution of counts in 211 handkerchiefs. The mean count of the whole series is 68,000 for a $^1/_2$ min. shaking. These figures represent about half the total numbers of particles which could be shaken from the handkerchiefs by prolonged agitation, and give an average figure of 136,000 for the total number of particles which could be removed by this means. The counts follow a log-normal distribution. The subsidiary peak of counts less than 2000 is due to a certain number of volunteers who did not use their handkerchiefs at all.

Correlation with Nasal Discharge.—Table I shows the relationship between the average counts of particles, shaken from handkerchiefs, classified into groups on the basis of the degree and type of nasal secretion of the user. There is but small difference between the total counts in the various groups, suggesting that the daily output of bacteria from the nose during a cold does not differ much from the normal output.

TABLE I—RELATIONSHIP BETWEEN NASAL DISCHARG PARTICLE COUNTS AFTER MECHANICAL SHAKING HANDKERCHIEFS FOR $^1/_2$ MIN.

Nasal discharge during use of handkerchief	No. of handkerchiefs	Count	
		Average	Range
Normal	122	68,000	0–420,
Slight serous ..	37	60,400	13,600–300,
Profuse serous ..	37	59,600	6400–192,
Purulent	15	94,000	2400–300,

DIE-AWAY RATES OF AIRBORNE PARTICLES FROM HANDKERCHIEFS IN THE PRESENCE AND ABSENCE OF AERIAL DISINFECTANTS

Method

To assess the size of the particles and their susceptibility to disinfectants, experiments were made as follows. Two or three handkerchiefs were shaken at the same time to give a sufficiently high initial count in the experim room. Half a minute was allowed for the co particles to settle, and then air sampling was begun a continued for 12 min. During measurements of natural die-aways serum-agar plates were exposed in room. In killing tests the disinfectant was liber at the end of the first minute of sampling. The relat humidity of the air was measured before and after e experiment. Low relative humidities were obtained b the use of a silica-gel air-drier, and high humidities b spraying water into the air. The plates were incubat for 24 hours at 37°C, and the slit sampler plates were the divided into $^1/_2$ min. sectors and counted. The successi $^1/_2$ min. counts were plotted on graph paper for the determination of the die-away rates and of the killing-rates due to the disinfectants.

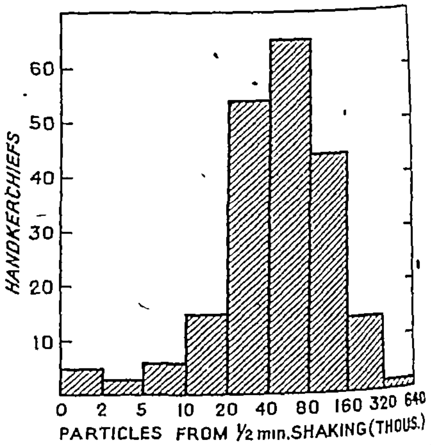

Fig. 2—Histogram of bacteria-carrying particle counts from used handkerchiefs shaken for $^1/_2$ min. each.

Results

The removal of bacteria-carrying particles from t air approximated to a logarithmic law such that t numbers removed in successive short intervals of t were proportional to the numbers present at the b ning of each interval—i.e.,

$$N = No\,e^{-kt}$$

where *No* is the number present at time $t = o$; k constant; and *e* the base of natural logarithms. If several processes which individually lead to the rem of bacteria in a logarithmic manner are taking p simultaneously, the total rate of disappearance (or d away rate) is equal to the sum of the rates due to e process. Thus, in an experiment using a disinfect the total rate of die-away will be a combination of rates of removal due to settling, ventilation, and de by disinfection. In these experiments the ventilat rate of the chamber was measured and found to be 0·4 per hour, which is negligible compared with rates of removal by settling or disinfection. The val of the settling rates were therefore taken as equival

Inguinal Hernia

THE repair of damage to a simple sphincter is ficult enough. In the case of the inguinal ring. e sphincter is far from simple: it bears some emblance to one half of an iris diaphragm, and body is quite certain how that diaphragm works. it is surprising that surgeons do on the whole tain better results with inguinal herniæ than nateurs obtain with the works of their cameras.

The anatomy of the human groin has long been own in great detail, and anatomists and surgeons ree on the main features of its architecture. The ysiology of the inguinal canal, by contrast, remains a state of flux, and each operator varies the details his repair according to his surmises as to the action of the well-known structures of which the nal is composed. Even the most obvious questions e still subjects of controversy. For example, nat is the real barrier to hernia formation in normal ople—is it the musculature of the internal ring. is it the transversalis fascia? Does the cremaster ay an important part in preventing hernia, or does presence facilitate the onset of rupture? If the mponents, muscular and tendinous, of the conjoint ndon act as a sphincter, it must be agreed that they e only half a sphincter; is then the opposite side that sphincter Poupart's ligament, or is it (as . F. LUNN[1] has suggested from his comparative ıdy of the inguinal region) Cooper's ligament and e superior ramus of the pubis? And should we erefore throw not only Bassini's bag but also his ggage overboard, cease using Poupart's ligament one pillar of our hernia repairs, and use Cooper's ament instead as the foundation of attempts to rrow the internal inguinal ring? Do the fascial ngs which LYTLE[2] emphasised really act as a third nincter inside the ordinarily described internal g?—One could fill a page asking such questions, of which require an authoritative answer if hernia erations are to have a proper scientific basis and eir disturbing recurrence-rate is to diminish.

There is one point in the operative repair of hernia ıich is everywhere accepted—namely, that narrow-cked sacs must be completely removed. But ost herniæ require something more than simple rniectomy if recurrence is to be avoided. The ditional repairs needed attempt either or both of o things—reconstruction of an inguinal sphincter blocking of the "hole" through which the hernia s emerged. The most thorough recent attempts to construct a sphincter mechanism have been by ANDON[3] and DOUGLAS.[4] BRANDON divides the ternal oblique at the medial end of its origin from oupart's ligament, moves the cord laterally, and reattaches the muscle. DOUGLAS has lately described in our columns an operation whereby the testis is dissected free from the scrotum, and, on the end of the spermatic cord, is threaded through a hole made in the internal oblique 4 or 5 cm. above its lower border; after which the testis is replaced in the scrotum. Ingenious as these methods are, the new sphincters are crude by comparison with Nature's efforts, and the late results of the operations are not yet known. At the present moment the method of blocking the defect through which the hernia emerges seems more popular. The weak point in this procedure (its crudity needs no comment) is that the cord still has to emerge from the abdomen, and the blocking operations therefore cannot be complete. When BRANDON and DOUGLAS have contrived their new sphincters, they can proceed to a complete blockage of the old "hole" (which DOUGLAS does with tantalum gauze). But if the cord retains its anatomical site, the best that can be done is to close most of the hole, leaving the internal oblique and transversalis (which have already failed once at this job) to guard a smaller aperture than before. Obviously these muscles must not be further damaged during the repair, and the frequent failures of Bassini's operation are probably due to the fact that the tight sutures approximating the internal oblique to Poupart's ligament kill the muscle fibres within their grasp.

Modern repair operations of the "blocking" type use various materials. Normal structures in the neighbourhood may be sutured in new positions to narrow the gap, but it is uncertain how often they retain both their new position and their old function. Autogenous fascia, locally obtained or imported from the thigh, in sheets or in strips, may be employed. Foreign materials—metal, silk, and nylon—are fashionable at present, and we have recently published papers describing the use of all three. MAINGOT[5] has recorded in detail his technique with floss silk, which has given excellent results. MOLONEY and his colleagues[6] believe nylon to be better, because it is homogeneous and smooth, and because a chance infection of a wound, which may linger for many months in the interstices of silk, will heal without the nylon requiring removal. Whether silk or nylon is used, the repair is usually by a darn, so as to avoid tension in the fibres and any possibility of strangulating muscle fibres. Those who have closed a hole in a sock with a few tight sutures will appreciate the superiority of the darn in that situation, and there is reason to suppose that the body also appreciates the darn rather than the suture for the closure of gaps in its fabric. Unlike the sock, it will assist the darner by filling in interstices with fibrous tissue.

The latest comer in the ranks of foreign materials for hernia repair is poly-ethylene sheeting, a plastic whose use is described on another page by WALTER THOMPSON. It is easy to shape and remains rigid in the tissues, but at first sight it seems to lack an advantage of tantalum gauze to which DOUGLAS refers, in that it has no meshes through which fibroblasts can grow to anchor it firmly in position.

Reviews of Books

Thorpe's Dictionary of Applied Chemistry

(4th ed.) Vol viii *Methal—Oils, Essential.* London: Longmans, Green. Pp. 679. 80*s.*

THIS splendid work is of value not only to chemists but also to many other workers in medical and biological fields. So wide is its scope that few would fail to find pleasure in dipping into it. The eighth volume follows the same lines as its predecessors. No less than 175 pages are given to a monograph on naphthalene, but the remainder of the book is liberally sprinkled with articles of biological interest. That on milk ably summarises the chemistry, biochemistry, technology, and (very briefly) the bacteriology of the "lacteal secretion of the milch cow." There is an account of nucleic acids by the late Prof. J. M. Gulland with G. R. Barker; J. H. Quastel contributes an account of biological nitrogen fixation, and B. C. J. G. Knight a well conceived summary of growth factors for micro-organisms. Biochemical articles include those on methionine and nicotinic acid. The electron microscope is treated in a simple and understandable way, and the article on molecular distillation is of interest in connexion with the preparation of fat-soluble vitamins. Hope springs when one reads of the astounding number of substances prescribed for the moth-proofing of textiles, while the essential oils bring the volume to a fragrant close.

Myotonia

Thomsen's Disease (Myotonia congenita), Paramyotonia, and Dystrophia myotonica: a clinical and heredibiologic investigation. EIVIND THOMASEN. Aarhus: Universitetsforlaget. 1948. Pp. 251.

IN this valuable and comprehensive work, translated from the Danish by F. B. Carlsen, Dr. Thomasen gives a clinical and physiological account of myotonia and describes the diseases in which it occurs, with particular reference to the associated non-muscular dystrophies. He has investigated the influences of these diseases on the social condition of the patients, and on their mental state; and in a personal study of 5 family histories of Thomsen's disease, he brings up to date the famous pedigree recorded by Thomsen himself, giving details of 106 descendants of an affected member of the family not available to Nissen when he published his edition of the pedigree 25 years ago. Four additional new pedigrees of Thomsen's disease include only 13 affected individuals, thus offering a contrast to the heavy incidence and clearly defined genetic character found in members of Thomsen's family. Since Dr. Thomasen has made an exhaustive search for cases in Denmark, the disease is clearly as rare as it is reputed to be.

In the genetics section he gives 21 new pedigrees of dystrophia myotonica, covering 1148 individuals of whom 874 are still living; 150 members are thought to have been affected. The appearance of antedating has been repeatedly noted in this disease, and is confirmed in this series. An attempt to grade the cases suggests that manifestations are increasingly severe in successive generations. Dr. Thomasen concludes that, from the clinical as well as from the genetic standpoint, Thomsen's disease differs fundamentally from dystrophia myotonica.

Die Sauna

VICTOR OTT. Dr. med., physician in the medical faculty, Zürich. Basle: Schwabe. 1948. Pp. 224. Sw. fr. 15.

THE Finnish bath, which is essentially designed to induce sweating, has been known since classical times. The usual procedure is to enter the hot-air chamber first, and to rest there on a couch until sweating begins. The skin may then be further stimulated by rubbing and pummelling, and a bundle of twigs is often used for this purpose in Finland. The body may then be douched with warm or cold water or be soaped before a short immersion in a nearby stream or lake. A further period of sweating may follow when the bather has got out of the water before cooling begins. Sometimes water is poured over hot stones at this stage to cause a sudden evolution of steam, but exposure to this is too exhausting for some subjects. At the end of the bath it is customary to rest for a while, and massage is sometimes given at this stage. Often the proceedings end with a square meal.

In recent years the Finnish bath has been stud doctors and has come into use beyond its count origin. The Swiss opened the first therapeutic ba 1941 in the physiotherapy department of the Univ of Zürich. There are now 150 public and nu private baths of this type in the country. The va sweat baths has been known in Switzerland sin sixteenth century, especially in chronic disorders as gout and rheumatism; but in Finland the ac medical indications for these baths have been num It is considered that the resistance of the Finn to cl changes and extremes is augmented by bathing, and regulations of the Finnish army prescribe a weekly even on active service. Dr. Ott has treated a nu of cases and concludes that sweat baths are val in numerous subacute—but not acute—infections, in asthenia and circulatory disorders. The baths st the circulation and body temperature and reduce w One of the outstanding benefits of a regular cou baths, even for healthy people, is the acquisition of greater tolerance to climatic changes and extremes.

The Venereal Diseases (2nd ed. London: Macm 1948. Pp. 360. 21*s.*).—This edition maintains the h standard of its predecessor, and has been brought up date with two additional chapters on the use of peni in the treatment of gonorrhœa and syphilis. The sect on non-gonococcal urethritis has been extended, and Reiter syndrome receives adequate description. Dr. James Marsha presents the venereal diseases, and those other condition commonly dealt with in the practice of venereology, accurate and clearly, and the text is supported by ample illustrat

Handbook of Practical Bacteriology (8th ed. Ed burgh: E. & S. Livingstone. 1948. Pp. 624. 25*s.*).— of new methods such as the use of selenite F medi *S. typhi*, and new information about infections like blastomycosis or scrapie of sheep, have swollen this la guide by Prof. T. J. Mackie and Dr. J. E. McCartn it still retains the essential qualities of a handbook f who must housekeep for rats or wash glassware, b knowing how to distinguish the viruses of lymphocyt pseudolymphocytic choriomeningitis.

The Science and Practice of Surgery (8th ed. Lo J. & A. Churchill. 2 vols. 1948. Pp. 892 and 955. 25*s.* ea The day of the large single-author textbook of general su has passed. Even two authors can scarcely hope to co many fields, if they are to speak with authority on Mr. W. H. C. Romanis and Mr. P. H. Mitchiner, in the edition of their well-known book, have enlisted help with chapters on plastic surgery, X rays, anæsthetics, and va disease. Even so, the industry required of two men to and then revise a book of over 1800 pages must be prodi The book preserves its previous form but much of it has rewritten to bring it up to date. Thus the section on g infection contains a note on streptomycin; though the paragraph, recommending the intravenous injection of in unspecified quantity, provides a quaint contrast. might pick many small holes of detail in the book, b fact that this is its eighth rebirth is an effective ans carping criticism.

Treatment by Manipulation (5th ed. London: Lewis. 1948. Pp. 275. 25*s.*).—The new edition Timbrell Fisher's well-tried book contains much fresh m and 45 additional illustrations. In his preface he r readers that patients bedridden for years owing to rheumatic disease may respond to skilled manipulat recovering the use of their legs; and that they sho given the opportunity. Objections to the use of ma tion, he says, are commonly two. Doctors fear sho increased pain and stiffness for their patients: but untoward reactions are extremely rare in the pract experienced surgeons using manipulation. Secondly generally believed that physiotherapy can do as mu manipulation to restore function and full range of move Many patients, however, improve up to a point on ph therapy, but get no further; and for these manipulation achieve in five minutes more than physiotherapy could years. The book is clearly written, and splendidly illustr sk of rubber designed to fit closely over the mouth and e. Experimental patterns of half-mask with highly cient filters, designed to overcome disabilities in ion and use of tools during wear, have not proved eptable in underground working conditions, and earch is now being directed to the design of less cient but simpler respirators in the hope that these l be accepted by workers. The simpler respirators l stop up to 90% of pathogenic particles, and their use uld at least reduce the risk of silicosis. However, n if miners agree to wear such a respirator, its use l not take the place of effective dust suppression, ich is the basic preventive measure. The aim should to make dust suppression in industry as complete possible, respirators being worn only in the occasional ances when suppression is impracticable.

ATHLETICS AND HEALTH

SEVERAL superficially simple problems associated with scular exercise still evade unchallenged explanation. titch," for example, was for centuries regarded as ociated in some way with the spleen, and classical olars have been prepared with quotations to show at the runners of antiquity underwent splenectomy or any rate some sort of attention to this viscus. Since ch can be right-sided, some favoured a diaphragmatic lanation, which in turn has been replaced by a usible one based on experiments at Guy's Hospital, rding to which there is a "physiological viscerois" and the site of the disability is in the ligaments pleural attachments. Yet athletic experts remain onvinced. Cramp is another teaser, for it arises ealthy young people under conditions which seem have nothing in common—during exercise, at it when turning or stretching, after yawning, when e position is held excessively long, or after profuse ating. Then there is march hæmoglobinuria, in which rcise is not the only factor, for the erect attitude is a sine qua non. These are some of the subjects ussed in *Manpower* for March–September, 1947, lished by the Union of South Africa, in a treatise nly the work of Dr. E. Jokl, whose official position Johannesburg has given him exceptional opportunities investigating the effects of exercise. This paper gives ne remarkable examples of athletes who have permed successfully for years free from symptoms and aware of gross cardiovascular lesions which necropsy s shown must have been present for a long time. Thus he iron man of South African rugby football," who lapsed and died after a strenuous game, was found to re a greatly hypertrophied heart with numerous rotic patches, an exceedingly narrow left coronary ery, a descending aorta less than half the usual calibre, d an advanced unilateral hydronephrosis. The ampion marathon runner of South Africa is a man of whose medical history includes rickets, scarlet fever, eumatic fever, malaria, bilharziasis, and inguinal rnia, and who has mitral and aortic disease—a reminder it aortic regurgitation is of *functional* benefit when perimposed on mitral disease. Examples of adjustment clude a Davis Cup lawn-tennis champion with severe ibetes; a girl of 19 with myasthenia gravis who with e aid of 'Prostigmin' played international hockey; d a professional gymnast with severe deformity of the est following several thoracoplastic operations.

British cardiologists have denied the possibility of eart strain" in the normal person, and their pronouncents, together with those of Adolphe Abrahams on the hletic side, are examined in the treatise. Clearly, llapse after exertion should be related not to the heart it to the vasomotor system. Some extremely efficient hletes are particularly prone to collapse, apparently cause of the general autonomic adjustment which the body undergoes during training. Responsible factors include a hot humid atmosphere, hypoglycæmia, orthostatic strain, reduced atmospheric pressure, malnutrition, and the effect of a recent infection. Despite the alarming appearance of a collapsed young adult, there is no reason to presume either cardiac strain or any permanent disability. Nor, apparently, can a full stomach be blamed for such attacks. Schoolboys have been known to prepare for a ten-mile cross-country run by eating a double helping of Irish stew and treacle pudding.[1] Common sense would condemn such a procedure, but it seems certain that a combination of exercise and a distended stomach alone will never cause fatal collapse in a healthy person. The position is very different if the coronary arteries are diseased or the myocardium degenerated, when a full stomach may be the ultimate cause of death, the rise in intragastric pressure eliciting a reflex constriction of the coronary arterial system with dangerous anoxæmia in a heart whose tissue respiration is already impaired.

TRACES OF THE PAST

THE last survivals of the control exercised by the Church over medical practice in medieval times are about to disappear from the statute-book. Among the many hundreds of dead Acts of Parliament which a Statute Law Revision Act will formally repeal is one enacted in 1511 which forbade physicians and surgeons to practise in London or within a seven-mile radius therefrom unless first examined, approved, and admitted by the Bishop of London or the Dean of St. Paul's. The bishop and the dean were to call to their aid "four doctors of physic and for surgery other expert persons in that faculty." In 1310 the Council of Treves had given the bishops authority over medical practice, but now, two centuries later, their supervision needed to be reinforced by Parliament in England. The preamble to the Act of 1511 discloses contemporary conditions in the following terms:

> "Forasmuch as the science and cunning of physic and surgery, to the perfect knowledge whereof be requisite both great learning and ripe experience, is daily within this realm exercised by a multitude of ignorant persons of whom the great part have no manner of insight in the same nor in any other kind of learning, some also can no letters on the book, so far forth that common artificers as smiths, weavers and women boldly and customably take upon them great cures and things of great difficulty in the which they partly use sorcery and witchcraft, partly apply such medicine unto the disease as be very noxious and nothing meetly therefor, to the high displeasure of God, great infamy to the faculties and the grievous hurt, damage and destruction of many of the King's people, most specially of them that cannot discern the uncunning from the cunning."

In spite of their incidental belittlement of the female practitioner, it is sad to say farewell to these sonorous Tudor phrases, though something remarkably like the last recital now stands in the much briefer preamble to the Medical Act of 1858 which opens with the pronouncement that "it is expedient that persons requiring medical aid should be able to distinguish qualified from unqualified practitioners."

Outside the seven-mile radius the Act of 1511 entrusted the examination and approval of prospective practitioners to the bishop of the diocese, or, in his absence, to his vicar-general, "calling unto them such expert persons in the said faculties as their discretion shall think convenient." A proviso safeguarded the rights and privileges of the universities of Oxford and Cambridge. And now the Act of 1511 is to vanish with the assent (according to the evidence submitted to the Joint Committee) of all the high authorities concerned—on the ecclesiastical side the Bishop of London, the Dean of

An Unfair Burden

To provide for superannuation, doctors in the National Health Service are liable to a deduction of 6% from their net remuneration from State sources, to which the Government will add another 8%. For the well-established practitioner the sums in question will be substantial: for example, if a doctor is earning £2400 from his N.H.S. practice, and a third of this is regarded as practice expenses, there will be a deduction of £96 from his income, the additional contribution from the State being £128. Before July 5, when there was no official pension provision for doctors, most medical men found it necessary to take out heavy insurances to safeguard their families and provide for their own retirement. Under the new régime it was clearly going to be difficult for them to continue these insurance commitments when large sums were deducted from their incomes for superannuation purposes. Accordingly arrangements have been made whereby, between now and Oct. 4, practitioners may (subject to conditions set out in the official leaflet S.D.D.) exercise an option to remain outside the superannuation scheme, pay no portion of their income to superannuation, but receive instead the 8% State contribution towards the maintenance of approved insurance policies.

Attention is drawn to this option in a letter which we publish this week from a medical insurance consultant. Clearly there may be definite advantages in it, especially perhaps for the doctor who is already well insured but will have few remaining years of service to count for superannuation. No doubt many doctors thus situated will welcome the chance of opting out of the superannuation benefits and receiving very present help towards their expensive insurance premiums. But there is another group whose need is even greater, and who can, nevertheless, receive no relief under the regulations as published. Many younger men have borrowed heavily in order to buy a practice, and for this purpose they have been required to insure their lives for considerable sums. The premiums they are paying sometimes represent a high proportion of their budget, and it may be almost impossible for them to go on paying these premiums if they also have to forego 6% of their income for superannuation. These are the very men who might find the 8% of State money paid towards insurance premiums most acceptable. Yet they do not qualify to receive this help, because their policies are technically assigned to the bank or to the insurance company that has lent them money to buy their practices. Many of these doctors belong to that group, enduring financial hardship, for whom the Government have promised early payment of compensation. If it had been possible for this compensation to be assessed and paid by Oct. 4 they would be in a position to have their policies released from assignment to their creditors, and could then exercise their option to keep these policies in being as an alternative to superannuation. As any such settlement is manifestly impossible in so short a time, this relief is withheld from them, and some whose budgets are already closely drawn will face certain insolvency if they must bear the double load. While it is obvious that if insurance is to take the place of superannuation and be the chief means of provision for retirement, insurance policies must not be surrendered before maturity or be assigned to another person, it seems that considerable latitude should be allowed in these particular cases. The assignment is directly attributable to a loan the date of whose payment (and the consequent redemption of the policies) depends on the date of payment of a sum of compensation promised (and guaranteed) by the Government themselves. It should not be hard to lay down conditions whereby the ultimate use of these policies for the benefit of the doctor and his dependants could be assured, even though the policies had temporarily to remain assigned to the bank or other reputable lender pending the payment of compensation.

This is certainly a matter that needs attention urgently. A rapid and equitable solution might materially reduce the numbers of the young doctors to whom the early payment of compensation on grounds of hardship will otherwise be essential. Failure to find a solution will place an unfair burden on many harassed men, including many returned from war service, who, with growing families, are now striving to establish themselves in practice.

Annotations

HOSPITAL RECORDS

NEARLY twenty years ago, when the old poor-law institutions were transferred from the boards of guardians, their records were in some instances mutilated or even destroyed in the process. Today a transfer on a much larger scale is taking place: hospitals of every kind—voluntary and municipal, big and little, new and old, general and special—are passing out of the care of their guardians into the smooth hands of the regional hospital boards. These hospitals possess records. In the long march of history the small hospital is just as important as the great, and what is new in 1948 may be treasured in the 21st century. Minutes of boards of management and of staff meetings, matrons' reports, notes of operations, diet sheets, patients' case-records, accounts, and other routine commentaries may seem drab enough just now, when there is little space for storage and much demand for salvage; but they are the stuff out of which social history is made.

Hospital records should be carefully preserved, at least until they have been reviewed by an expert. Many local authorities have record offices staffed by trained people who would take pleasure in sifting material of this kind. There is ample scope for voluntary work on the part of men and women who have an interest in local history. Let us not throw away this unique opportunity of service to history.

RESPIRATORS AND DUST DISEASES

A CORRESPONDENT this week asks why writers on pneumoconiosis do not mention the use of a simple mask, such as nurses wear during operations, as protection against the inhalation of dust. It is virtually impossible to design a completely efficient dust respirator which does not impose some discomfort or disability on the wearer; and tests on miners and other workers have shown that they will not tolerate one which is uncomfortable. Simple gauze respirators similar to a surgeon's mask are acceptable to some miners, but unfortunately they are almost useless in stopping the passage of pathogenic dust particles, which are less than 5μ in diameter. The official Mark IV dust respirator is much more efficient; but very few miners are willing to wear a respirator of this type, which incorporates a half of rubber designed to fit closely over the mouth and

Experimental patterns of half-mask with highly nt filters, designed to overcome disabilities in and use of tools during wear, have not proved table in underground working conditions, and ch is now being directed to the design of less nt but simpler respirators in the hope that these e accepted by workers. > "Forasmuch as the science and cunning of physic and surgery, to the perfect knowledge whereof be requisite both great learning and ripe experience, is daily within this realm exercised by a multitude of ignorant persons of whom the great part have no manner of insight in the same nor in any other kind of learning, some also can no letters on the book, so far forth that common artificers as smiths, weavers and women boldly and customably take upon them great cures and things of great difficulty in the which they partly use sorcery and witchcraft, partly apply such medicine unto the disease as be very noxious and nothing meetly therefor, to the high displeasure of God, great infamy to the faculties and the grievous hurt, damage and destruction of many of the King's people, most specially of them that cannot discern the uncunning from the cunning."

In spite of their incidental belittlement of the female practitioner, it is sad to say farewell to these sonorous Tudor phrases, though something remarkably like the last recital now stands in the much briefer preamble to the Medical Act of 1858 which opens with the pronouncement that "it is expedient that persons requiring medical aid should be able to distinguish qualified from unqualified practitioners."

Outside the seven-mile radius the Act of 1511 entrusted the examination and approval of prospective practitioners to the bishop of the diocese, or, in his absence, to his vicar-general, "calling unto them such expert persons in the said faculties as their discretion shall think convenient." A proviso safeguarded the rights and privileges of the universities of Oxford and Cambridge. And now the Act of 1511 is to vanish with the assent (according to the evidence submitted to the Joint Committee) of all the high authorities concerned—on the ecclesiastical side the Bishop of London, the Dean of

---

St. Paul's, and the Legal Board of the Church Assembly, and on the secular side the Privy Council, the Ministry of Health, the Royal Colleges of Physicians and Surgeons, and the General Medical Council. The Act seemed still to have some spark of vitality when referred to in D'Allax *v.* Jones in 1856, but the subsequent passing of the Medical Act presumably quenched whatever was still smouldering. With the 1511 Act will also disappear section 3 of the "Acte concerning Phisicions," passed some eleven years later. This section explained that in dioceses outside London "it is not light to find alway men able sufficiently to examine (after the statute) such as shall be admitted to exercise physic in them." By way of remedy it directs that, before anyone is to practise physic in England, he must first be examined in London by the president of the recently incorporated College of Physicians (presumably Thomas Linacre) and must be able to show testimonials of his approval, though there is a saving for any graduate from Oxford or Cambridge "which hath accomplished all things for his form without any grace."

Herbalists will be pleased to know that, though the Act of 1511 is doomed, the Act of 1542 is left untouched, which in some degree excepted therefrom those "honest persons, as well men as women, whom God hath endued with the knowledge of the nature, kind, and operation of certain herbs, roots, and waters." There still will remain on the statute-book, therefore, the long preamble which unkindly accuses the orthodox admitted surgeons of attending too closely to their fee-books. "The most part of the persons of the said craft of surgeon," concludes the preamble, "have small cunning, yet they will take great sums of money and do little therefor, and by reason thereof they do often times impair and hurt their patients rather than do them good."

In 1948 the rival claims of the qualified and the unqualified are still occasionally contrasted; the restrictive mood of 1511 is not yet fully reconciled with the toleration of 1542. Historians have little use for statute-law revision which eliminates the traces of the past. It cannot be contended, however, that the Act of 1511 is of value as living law. It would disqualify every registered practitioner who is qualified today.

ALLEGED NEGLECT

IT is none too easy to find good homes for mentally retarded children, and there are disquieting features in the charge of neglect successfully brought against Miss G. E. Sherwood, of Potters Bar, by the Royal Society for Prevention of Cruelty to Children. Briefly, the case for the prosecution was that one of the children in the home was found to be emaciated but gained weight rapidly when transferred to hospital. The case for the defence, supported by the expert evidence of Dr. A. F. Tredgold, was that children of low-mental grade often fail to make full use of the food given them: the disorders of development responsible for severe mental deficiency are liable to interfere with physical functions, including metabolism and digestion. The other children in the home seem to have been well cared for; and parents (including doctors) have testified to Miss Sherwood's devotion to her work. But the jury, who had been shown a photograph of the wasted child, found her guilty, and she was sentenced to a day's imprisonment.

This defendant seems to have broken the rules about licensing and periodical medical examination; there may also have been mismanagement; or a degree of neglect. But sometimes malnutrition of defective children—with results likely to horrify a jury—cannot be prevented; and this verdict will not increase the confidence of other people who may be trying to look after mental defectives whose power to assimilate food is faulty. Often the strictures of parents—who may be suffering under a load of half-conscious guilt for having relinquished the chi at all—do nothing to make the nurse's task lighte Miss Sherwood's long record of good and conscientio care of mentally defective children has not saved he from adverse judgment over one difficult case.

COMPENSATION

GENERAL practitioners who joined the National Heal Service by July 5 and were previously working a principals are entitled to compensation for losing th right to sell the goodwill of their practices.[1] It will b remembered, however, that compensation is payable t doctors (or their personal representatives) who hav retired or died since the passing of the Act on Nov. 6, 194 provided their practices have not since been sold in part or whole. Hence, as compensation cannot be pai twice over, a doctor who has succeeded to such a practic without purchase, will have no claim to compensatio

Claims for compensation must be submitted in prop form by Oct. 31: only in special circumstances caus unavoidable delay will a later claim be admitted, an *in no case will it be considered after April 30, 194* These dates have been fixed, and are to be strictly adhered to, because until all claims are registered and assessed it will be impossible to calculate and distribute the compensation due to any claimant. Further grace would thus defeat the present intention of having all claims assessed and agreed, and the amount of compensation individually determined, before July 5 next year.

The annual value of the goodwill (known also as the "annual loss") will be taken as being the average gro yearly receipts of the practice during the last tw accounting years before the appointed day. The receipts need to be certified by a qualified accounta or alternatively the certificate of the approp Inspector of Taxes will be accepted. In the cas practices purchased after the beginning of the tw accounting years immediately before the appointed da the annual loss will be the average gross yearly recei of the practice as estimated for the purpose of th purchase. A committee of five (three of whom will b medical practitioners) is to be set up to deal with a claims that need special consideration. As soon a possible after the decision on a claim is reached th claimant will be told what the Minister regards as th annual value of his practice for compensation purpo It will be open to him, if aggrieved by this decision, to apply (within fourteen days) to have his annual lo determined instead by arbitration.

When all claims have finally been received and determined, they will be added together to find th aggregate annual loss claimed by the sum total of gener practitioners. Only when this figure is known will i be possible to divide the sum so obtained into th global sum voted by Parliament for the payment o compensation, and so determine the factor (equival to the number of years' purchase) on which the act amount of compensation payable in respect of ea practice, or share of a practice, will depend. Once t factor is known, and the actual amount calculated each practice, the practitioner will be notified. Wh a practitioner has already retired or died, compensati will be payable for claims as soon as may be after t amount has been ascertained: in other cases it w be payable on the death or retirement of the practition —whichever comes first. (Retirement means retirem from practice as a medical practitioner providing gener medical services under part IV of the Act.) Provis is also made, however, for advance payment of part o all of the compensation where hardship would otherw

---

If this hardship is due to heavy charges in respect ns raised for the purchase of the practice, the nt must forward particulars of the amount of an outstanding, the interest charges, the rate of ment of principal, and the cost of insurance ums (if any) taken as condition of loan. All such ation will be treated as confidential, as will also rticulars submitted of practice earnings and rship shares. Claims for advance payment on ds of hardship may be submitted at any time.

rest will be payable at the rate of $2^3/_4$% per annum, come-tax, as from July 5, 1948. The first pay- will be made on July 5, 1949, but thereafter yments will be made half-yearly, on Jan. 5 and . The regulations recognise and allow for modifis that may have to be made by amending legislafter the report is received from the legal committee sent investigating the special position of partner-

Nevertheless it remains necessary for partners, y with single-handed practitioners, to submit Oct. 31 certified particulars of their gross annual ts. This they are advised to do without undue as soon as they receive the appropriate claim form their executive councils.

MOTHER OF ORTHOPÆDIC NURSING

w often great pioneers must find that their success ken them by surprise. It can hardly have occurred nes Hunt, when she opened a small convalescent for children in the Shropshire village of Baschurch, she was about to become the founder of orthonursing. Indeed, the whole scheme was started t at random. Daughter of a positive and eccentric er, she was one of a family of eleven. As a child eveloped joint disease, but recovered sufficiently in as a nurse in the Royal Alexandra Hospital, and at Salop Infirmary, and to become a district —no sinecure at any time, but in those days a ne trial of strength. "One day," she wrote in nemoir, "mother broke it to me that she was ing too old and deaf to do her work in London, hat she intended to live with me. This was rather w." A new plan had to be made: and the conent home was opened on the joint income of er and daughter, plus subscriptions amounting to 2s. 3½d. In his book, *Doctors Differ*,[1] Dr. Harley ams describes the vitality of this ramshackle place. When space ran short the children were d in a shed in the garden, and did astonishingly forthwith the open-air régime became a principle eatment at Baschurch. When the advice of an pædic surgeon was needed, Agnes Hunt, crippled by a recurrence of her old disease, shepherded a crew of splinted children by train to Liverpool, e railway porters wheeled them to the Southern ital; and there she met Robert Jones. After a uch visits she tentatively suggested that he should ne visiting surgeon to her odd hospital; he accepted, then began one of the most fertile partnerships in cine. "Robert Jones performed the operations Miss Hunt performed the rest." She was naturally oped for the task; she had fun, and saw to it that hildren had fun; and she had experienced what alled "the great education of pain." She needed lk of reablement to teach her that crippled people arming for a struggle; the children in her hospital plays, learned football, and were taught the nts of trades. Mr. G. R. Girdlestone[2] has written ose early years: "We who walked with Robert s and Sister Hunt in the original Baschurch Hospital very fortunate—those were golden days! The ition was in the foundry, white hot and spilling over!" The hospital with the old shed in the garden grew, during the 1914-18 war, into the Auxiliary Orthopædic Hospital at Baschurch, with Agnes Hunt as commandant; and later into the Robert Jones and Agnes Hunt Orthopædic Hospital near Oswestry.

In 1924 she thought her work was to be permanently interrupted by illness; but not a bit of it: she was at the beginning of a long career in organising aftercare for cripples, in the course of which she founded the Derwen Cripples Training College. Dame Agnes lost her surgical collaborator in 1933 but herself survived to the age of 81, dying last week at her home in Baschurch.

THE ENGLISH LOCAL PRISON

"THE truth is that our prisons have beaten the Prison Commissioners. They were built for punishment in solitary confinement; and the hopeless congestion within the confining walls makes any real modification well-nigh impossible. A prison is little more than a disciplined slum, with most of the disadvantages of slum life."

These words come from a foreword, by Mr. George Benson, M.P., to a new pamphlet[1] from the penal reform committee of the Society of Friends. There is not a prison in England that is not overcrowded, even by 19th century standards; and the remedy, he suggests, is only by real reform—a rapid increase in the number of minimum security camps. The accounts here given by Quaker prisoners, imprisoned for refusal to fight in the war, are sufficiently vivid and disquieting. During the war advances made in earlier years were swept away, staff was scarce, and the hours spent by prisoners in workshops were greatly reduced, until some 18 or 19 hours in the 24 were spent alone in the cells. Though some of the lost ground has been regained, and the educational and library services have been improved, no extra services can make up for lack of staff and crowded quarters. The standard of hygiene is evidently shockingly low. Twenty men queue to empty their chamber-pots in a closet which is often stopped up; toilet paper, toothbrushes, combs, and even handkerchiefs are hard to come by; a prisoner has known what it is to go five weeks without any change of socks or shirt, or even a towel; Wandsworth prison was infested with bugs in the bed boards; baths are dirty, cleaning materials not provided. Apart from the mental effects of living for long terms in such surroundings, prisoners are not well supervised physically. The medical inspection on admission is often quite trivial and the examination on discharge even more perfunctory. Sometimes the newly admitted prisoner is not even required to undress. "The examination for venereal disease," writes one prisoner, "consisted in the question, 'Have you any discharge?'." Though occasionally a prisoner speaks well of the diet, food is often poor and badly prepared, with too little in the way of fresh fruit or green vegetables; and none is served between 4 P.M. and breakfast.

These are not conditions of life under which anyone could profit by measures for his reform; and many prisoners suffer deterioration rather than improvement in their outlook. Some indeed become mentally ill. Mr. C. F. Carter, who edits the pamphlet, urges that it is time for Britain to catch up with the best standards in other countries. "She will not do so at the snail's progress of the last thirty years."

Sir **WILLIAM GILLIATT** has been re-elected president of the Royal College of Obstetricians and Gynæcologists.

Surgeon Rear-Admiral C. E. **GREESON** has been appointed medical director-general of the Navy in succession to Vice-Admiral Sir Henry Colson who retires at the end of this year.

BRITISH EMPIRE CANCER CAMPAIGN

ANNUAL REPORT

A message of appreciation and confidence from H.M. the King accompanies a second volume[1] of the report covering the year 1947 and commemorating the 25th birthday of the campaign.

Several of the individual items recorded here have been noticed previously in these pages.[2] The scientific advisory committee anticipates even greater activity in research as the outcome of planning, and of training and exchanging personnel with other countries. An integrating subcommittee is to study the plans of all the standing subcommittees in order to coordinate and make recommendations for future work. The main directions of extension are to be in virus and clinical fields.

PENILE CANCER

Prevention, early diagnosis, surgery, and X-radiation remain the solutions of choice in human therapy. Prevention, it appears, may have to be begun far earlier than has hitherto been supposed. To his previous account of tumours whose incidence varied with the social scale, and thus probably with attention to, or neglect of, hygiene,[3] Sir ERNEST KENNAWAY, F.R.S., has now added some new data on cancer of the penis. This has long been known to be avoidable when circumcision is performed by Jewish rites, but it is apparently not preventable when the operation is done in conformity with Moslem custom. The difference in results is explained by the difference in age at operation: in Jews this is undertaken at the age of 8 days, whereas in Moslems it is undertaken at the age of 14 years or later. This puts back the time for prevention very close to what Peyton Rous has described as the only ivory tower that man ever knows—the uterus. But even this haven of immunity from carcinogens has been suspect since urethane has been reported to exert its tumour-provoking properties through the placenta.[4] Probably other carcinogens are able to travel the same route; it has always been surprising that on the whole Bittner's agent is held back.

PULMONARY CARCINOMA

Prevention of cancer of the lung is urgently needed, for its incidence is increasing at a striking rate; the increases each year from 1944 to 1946 were 412, 489, and 783. This continued rise has suggested an investigation into the composition of atmospheric dust, which has been initiated by the Medical Research Council and is being carried out by Sir ERNEST KENNAWAY and his team. The pertinacity and fecundity of this indefatigable alliance must be an inspiration to the discouraged. Inquiry may show that the horse has already left the stable; for if the latent period of lung cancer is anything like that of other diseases, its cause was in operation long ago. But although gross atmospheric pollution may be decreasing, the use of oil-fired boilers is now on the increase and may conceivably be a factor in causation; and, as the Kennaways themselves have pointed out, there is also a general increase in cigarette smoking.

PROSTATE

Unfortunately, the clinical-cancer research committee finds that the number of patients who consult a doctor within the first three months of prostatic cancer is as low as for other sites (only 53·5%), and that the in whom the disease is of over 6 months' standing first seen is as high as 20%. Metastases may be p in 27% of all cases when first examined; and enlargements regarded as benign, when excised, to be malignant. The extensive data on trea and follow-up of cases in the London hospital recorded were collected before the introduc œstrogen treatment. A later series, including th of treatment, will provide a valuable comparison.

No rationale of the action of œstrogens has yet app and experimental attempts to elucidate this action been frustrated, according to Mr. E. S. HORNING, by the tendency of transplantable prostatic carci to keratinise spontaneously as well as under the inf of stilbœstrol, and even when grown alone in cast mice. The newer therapeutic agents, like œstro may modify cancer in some of its aspects, both p logical and symptomatic, but they fall far shor controlling the disease in the sense of regul dominating, or doing away with it.

Annual Meeting

AT the annual meeting in London on July 19, a mes was received from H.R.H. the DUKE OF GLOUCESTE president of the campaign, who expressed gratificati that Lord Horder's recent broadcast appeal had result in the receipt of over £10,000. He referred to th tour of the United States and Canada which is be made by a delegation headed by Lord Horder, chairma of the scientific advisory committee.

Mr. J. P. LOCKHART-MUMMERY, chairman of t executive committee, who proposed the adoption of annual report, said that since its foundation in the campaign had grown enormously; and one of original aims—the coordination of research—had almost completely achieved. He agreed with Horder's suggestion that a short, non-technical of the campaign's work ought to be published f information of the lay public; but, as editor annual report since the campaign's foundatio have found the difficulties—and shall I say the dan of producing one in simple language, insurmount In the United States a Federal grant of no les 14 million dollars had been made for cancer research education; and the campaign had trebled the am spent annually on research.

The Garton medal and prize was presented by Vis Hailsham, chairman of the grand council, to Prof. Dodds, F.R.S., who returned the prize as a contribu to the campaign's funds.

PHARMACOPŒIAL NAMES AND APPRO NAMES

THE General Medical Council has issued a pamp setting out the names of drugs made official fo first time by their use as the titles of monograph *British Pharmacopœia*, the new edition of which into force on Sept. 1.[1] Names for certain other for which no official monographs are provided, hav published as approved names, the intention bein if any of the drugs is eventually described in the *Pharmacopœia*, the approved name shall becom official title. Some of the other names are reg trade-marks. It is hoped that the approved will be generally adopted and used in prescribing introduction of new names for substances having ph copœial names or approved names is especially cated; but if a manufacturer should desire to under a proprietary name a drug for which an appr name has been provided, it is strongly recomme that the label shall bear the approved name of substance in letters no less conspicuous than the which the proprietary name is printed or written.

---

following names have been made official by da to the *B.P.*, 1932, and by the *B.P.*, 1948 :

Pharmacopœial names	*Other names*
sol	Stovarsol
aenaphthone	Kapilon-Oral : Prokayvit
ocaine Hydrochloride	Decicaine
crine Hydrochloride	Acramine Yellow
tamine	Benzedrine
tamine Sulphate	Benzedrine Sulphate
thol	Avertin
ine Sulphate	Butyn
Aminobenzoate	Butesin
hol	Doryl
fon	Yatren
caine Hydrochloride	Nupercaine
cortone acetate	Doca
e) Injection of	Perabrodil
an	Butolan
aol	Cignolin
fying Wax	Lanette Wax SX
mine Tartrate	Femergin
arbitone	Evipan
arbitone Sodium	Evipan Sodium
us Ointment	Eucerin (Hydrous)
l Oil	Lipiodol
l	Uroselectan-B
ol	Cardiazol
hthone	Kapilon
ine Hydrochloride	Atebrin : Quinacrine Hydrochloride, *U.S.P.* XIII
ine Methanesulphonate	Atebrin Musonate
yl, Injection of	Salyrgan
lphenobarbitone (Phemitone)	Prominal
gmine Bromide	Prostigmin
gmine Methylsulphate	Prostigmin
amide	Coramine
cin, Injection of	Pitocin
uin	Plasmoquine
arbitone Sodium	Nembutal
ine Hydrochloride	Dolantin ; Demerol
toin Sodium	Epanutin
terone, Injection of	Proluton
Protein	Protargol
Aurothiomalate	Myocrisin
ıen	Fouadin
cetamide	Albucid
cetamide sodium	Albucid Soluble
nilamide	Prontosil Album
apyridine	Dagenan ; M. & B. 693
in	Germanin ; Bayer 205 ; Antrypol
hylline with Ethylenediamine	Euphyllin ; Cardophylin
ntone Sodium	Pentothal Sodium
essin, Injection of	Pitressin
Ether	Vinethene
Alcohols	Hartolan Wax
Alcohols, Ointment of	Eucerin (Anhydrous)

following are new approved names :

proved names	*Other names*
ide	Cetyltrimethylammonium bromide ; Cetavlon
arbitone	5-Δ^1-Cyclohexenyl-5-ethylbarbituric acid ; Phanodorm
caprol	2 : 3-dimercaptopropanol ; British Antilewisite ; Bal
hylstilbamidine	4 : 4′-Diamidino-α-β-dimethylstilbene
ole	4-Cyclohexenyl-3-ethyl-1 : 2 : 4-triazole ; Azoman ; Triazole
enide	*p*-Aminomethylbenezenesulphonamide ; Marfanil
chol	Trimethylmethoxypropenylammonium bromide ; Esmodil is a 0·3% isotonic solution
phen	2 : 6-Dimethylthianthrene ; Dimethyldiphenylene disulphide ; Mitigal
midine	α : ω-(4 : 4′-Diamidinodiphenoxy) pentane
Pheniodol	α-Phenyl-β-(4-hydroxy-3 : 5-diiodophenyl)-propionic acid ; Biliselectan
Pholedrine	β-Methylamino-4-hydroxypropylbenzene ; Veritol
Proguanil	N-*p*-Chlorophenyl-N-*iso*propylbiguanide ; Paludrine
Propamidine	α : ω-(4 : 4′Diamidinodiphenoxy) propane
Sodium Stibogluconate	Sodium antimonyl gluconate ; Pentostam
Stilbamidine	4 : 4′Diamidinostilbene
Sulphadimidine	2-(*p*-Aminobenzenesulphonamido) 4 : 6-diamethylpyrimidine ; Sulphamezathine ; Sulphadimethylpyrimidine
Thialbarbitone	5-Δ^2-Cyclohexenyl-5-allyl-2-thiobarbituric acid ; Kemithal
Thiomersalate	Sodium ethylmercurithiosalicylate ; Merthiolate

PAY-BEDS IN HOSPITAL

UNDER the National Health Service Act nobody need pay for hospital care. But charges can be made to patients who ask for a bed in a single room or small ward (the so-called amenity bed) and to those admitted to pay-beds as the private patients of doctors belonging to the service. Regulations governing these charges have now been published.[1]

"*Amenity Beds.*"—Accommodation in a single room or small ward cannot be secured by payment unless it "is not for the time being needed by any patient on medical grounds." The charge is designed to cover part of the cost, and will normally be 6*s.* a day for a single room or 3*s.* a day for a ward with two or more beds. In hospitals where the average daily cost of an inpatient is less than 24*s.* these charges will be reduced.

Private Accommodation.—Provided it does not prevent their being used by any patient who urgently needs them on medical grounds, the hospital may set aside beds for patients who are prepared to pay the whole cost, being admitted as private patients under the care of their own doctor. If the hospital has insufficient data for estimating the cost of the accommodation thus set aside, the standard daily charge for such beds will be the average daily cost of an inpatient in the hospital plus 25% for a single room, 15% for a room with two beds, or 5% for a room with more than two. But since the patient will be paying privately for his medical attention it would not be reasonable for him to pay also for medical attention from the hospital staff. The standard daily charge will therefore be reduced by an amount representing the average daily cost per inpatient of the remuneration of the specialist staff, or (if the patient is admitted under the care of a general practitioner) of the whole of the medical staff.

Medical Fees Payable by Private Patients.—The Minister has laid down a schedule of maximum fees payable to doctors attending private patients in a hospital pay-bed. The following are examples :

Physician.—For the first consultation, 5 guineas ; for the first two days' attendance (including first consultation), 10 guineas ; for each subsequent day of attendance or consultation, 1 guinea. Total not more than 25 guineas.

Surgeon.—Cases involving operation : all services including operations and any necessary attendance—major operation, 50 guineas ; intermediate operation, 25 guineas ; minor operation, 10 guineas. Cases not involving operation : as for physician.

Obstetrician.—For booked cases, 50 guineas ; obstetric emergencies, 40 guineas.

Psychiatrist.—Deep insulin therapy (full course), 75 guineas. Special individual psychotherapy : first consultation, 5 guineas ; subsequent consultations, 3 guineas.

Anæsthetist.—For each operation, 2 guineas plus 10% of surgeon's fee.

---

al in the seventh addendum to the *British Pharmacopœia*, 32, but not included in the *British Pharmacopœia*, 1948.

[1] National Health Service (Pay-bed Accommodation in Hospitals &c.) Regulations. Statutory Instruments, 1948, no. 1490.

Pathologist.—Single examinations involving less than an hour's bench work, $1^1/_2$ guineas; multiple and more complicated examinations, 3 guineas; examinations with clinical consultations, 5 guineas.

Radiologist.—For investigation, various fees from 2 to 6 guineas. Radiotherapy, 3 guineas per treatment; total not more than 25 guineas.

Medical Practitioner, other than Specialist.—For a surgical operation, including all attendances and other services rendered, 7 guineas. For each consultation or day of attendance, 15*s.* Total not more than 15 guineas.

If the total charges made by "all the medical practitioners concerned in respect of one series of treatments of a patient for relief of the same condition exceeds 75 guineas" the charges of each shall be scaled down proportionately, so that the patient does not in fact pay more than 75 guineas.

These maxima, however, will not apply if the hospital is satisfied that the patient or his representatives have agreed with the practitioner to pay larger fees. The board of governors or management committee will secure, "as far as may be reasonably practicable," that not more than 15% of the hospital pay-bed accommodation (other than "amenity beds") is occupied by patients for whom there is no limitation of medical charges. If the pay-bed accommodation is less than 20 beds, 3 may be so occupied.

Private Outpatients.—The regulations lay down charges which the hospital should normally make for pathological, radiodiagnostic, radiotherapeutic, or physiotherapeutic services to private patients for outpatient treatment.

WORLD HEALTH ASSEMBLY

HAVING sat for a month, the assembly last Saturday concluded its first meeting, which was followed at once by the first session of the executive board of the World Health Organisation, with Dr. Aly Tewfik Shousha Pasha as chairman, and Dr. K. Evang and Dr. W. W. Yung as vice-chairmen. The director-general of W.H.O. will be Dr. Brock Chisholm, who has been executive secretary of the interim commission and was elected to the new office by 46 votes to 2. The interim commission's proposed budget for the coming year has been cut by 23% to 5 million dollars.

PHYSICAL EDUCATION

AN International Congress on Physical Education, Recreation, and Rehabilitation opened in London last week. Delegates from over 50 countries have been shown what is being done here.

On Tuesday representatives from the Commonwealth countries were entertained to luncheon at the Apothecaries' Hall by the Research Board for the Correlation of Medical Science and Physical Education.

Dr. FRANK HOWITT, the chairman, recalled that the board originated during the war with the aim of improving the utilisation of manpower. Since then it had concentrated largely on the physical education of young people and industrial workers, and many of its recommendations had been implemented by the Government. With the Nuffield Foundation it was now studying the care of adolescents in industry. He hoped that the present conference would result in the formation of a Commonwealth and Empire Council with the same objects as the board.

Mr. PHILIP NOEL-BAKER, Secretary for Commonwealth Relations, spoke of the value of physical education: he wanted to see the British, like the ancient Greeks, a nation of athletes. Mr. J. H. BEASLEY, Australian resident minister in London, felt that coöperation between nations would come best by joining in purposes like this that really matter to mankind. Lord WEBB-JOHNSON, P.R.C.S., said that the board was founded in difficult times; but such times provided the stimulus and led governments to spend money on real needs. He urged Ministers not to allow the disintegration of the Army's physical development centre for recruits, which was unique in the world. A government which talked of a National *Health* Service, rather than a mere *medical* service, must take account of the work of the board.

Public Health

Typhus in Northern Ireland

Two cases of typhus have lately been reported Omagh, co. Tyrone. When first seen by the medical officer, who, under the new health assumed responsibility for the control of infe disease on July 5, one patient was still in Omagh Hospital while the second had returned home. Felix reactions were done; in both cases there was agglutination of *OX* 19, slight agglutination of and no agglutination of *OX K.*

The patients' house was found, on investigat be unfit and verminous. There had been fre contacts between the infected family and roving gips tinker bands who frequent the patients' village an travels from the west of Ireland, where typhus is endemic. Though actual proof is still lacking, there little doubt that the disease, which has been shown of the louse-borne variety, came from these gipsies.

All contacts have been removed to hospital; steps are being taken to trace every gipsy band thr out Northern Ireland, and to treat them with So far no further cases have been reported, but all have been warned of the possibility.

The Health of Scotland

Reviewing 1947, the Department of Health Scotland calls it a fairly satisfactory year[1] The birt rate at 22 per 1000 was the highest since [illegible]; matern mortality at 2·0 per 1000 live births was the lowest o record; the crude annual death-rate was very litt altered from that in previous years; and the mortal rates in infants and children showed many satisf features, including a further decline in the mor and mortality of diphtheria. Poliomyelitis, br produced the largest outbreak ever experienced in land—1434 confirmed cases with 131 deaths enteritis was the cause of a slight increase in the mortality rate: in the 16 towns 1123 deaths we buted to infantile diarrhœa, compared with 642 The tuberculosis figures, as mentioned in our article last week, were also disturbing, with notifications compared with 9713 in the previous and a rise in deaths from 3984 to 4096. "We ha go back to 1928–32 to find comparable rates improvement gained between that time and the beg of the war has all been lost." Facilities for the tional treatment of tuberculosis were even less s factory than in previous years, principally because difficulty of obtaining nursing staff, and efforts are made to enlist more part-time nurses and ward ord "In one hospital," it is stated, "experiments were in running a ward on the hostel system by the pat themselves, with only nursing supervision."

Births and Deaths in June Quarter

The Registrar-General[2] reports that infant mort in England and Wales for the June quarter of established a new low record; the rate was 31 per live births. The previous lowest rate for any qu was 32 in the September quarter of 1947; and the previous rate for a June quarter was 39 in 1947.

The stillbirth-rate for the June quarter, 23 per total births, is the lowest recorded for any June qu in the corresponding quarter of 1947 the rate w

The number of live births registered during the q was 203,711, compared with 202,184 in the pr quarter and 235,174 in the same period last year corresponding rates were, respectively, 19·0, 18 21·9 per 1000 population.

There were 110,356 deaths in the quarter, repre a record low death-rate for any June quarter of per 1000 total population, compared with 11·0 for second quarter in 1947 and the previous lowest rat a second quarter of 10·4 in 1945.

In England Now

Running Commentary by Peripatetic Correspondents

r Stockholm hotel baths cost 3s. apiece, so everyone to huge sports palaces or gymnasia, somewhat like Greeks of old. I joined in such a throng, bought a et for 1 crown 25 öre (about 1s. 9d.), deposited my ables in an individual safe, and moved on to the ole bath-house. Imagine a swimming-pool surrounded vide alcoves two stories high and crowded with naked , lounging, reading, showering, climbing stairs, or nming. Middle-aged women fussed about shepherding n into the right pens and distributing towels. It ned that there were six men and one woman per alcove. ot knowing a word of Swedish, and realising that few nary Swedes know any other language, I learned the ine by a process of observation. The ritual was to and then go in succession from a hot moist room to ll hotter and moister one, in each sitting on a grand- d seat as at a football match, only nude and piring. I fought for every breath. Thereafter came y shower and a plunge in the pool below, which was real object of my visit. Naturally I got the order all ng, so an amazon had to drag me from the edge of pool and send me the right way round.

ecovering in my alcove afterwards I watched mas- ne Stockholm standing around in stained-glass udes discussing weighty problems. It was like the vre come to life. No Socrates graced this assembly; there were men of all ages, hairy or bald, thick or thin, gling with Apollos by the score.

is an impressive attitude of mind and custom that ain might well adopt in these days of chronic water tage; but somehow I cannot see us doing it.

* * *

uring the peripatetic wanderings on industrial arch problems of my younger days there was an epted but scientifically unsubstantiated convention I left behind a desolate and sorrowing family to be ced only by the return of paterfamilias laden with s. But at that time the gifts were relatively easy to ne by. There was rock in plenty to be had in Edinburgh toffee in Everton, with no personal points at stake, much attractive china in the potteries as one could ggle home with, and endless supplies of pretty cotton ks in Lancashire. Now, when one is not allowed to e one's sweet coupons away from home, when any sing clothing coupons must be accounted for on one's rn, and when the shops are full of things that our ort market won't touch, the buying of suitable sents may well absorb all one's spare time and spare h. However, finding myself the other week in the llands and knowing that my wife, with an optimistic on the English summer, wanted what is called a wim-suit," I determined to take a chance on that. efficient young lady sold me the very latest thing in on, and then, without batting an eyelid, warned me t the recipient should not on any account be photo- phed in it for in the resulting picture it would be quite nsparent. Sceptically, but slightly shaken, I took it ne, to be faced with the same story from my daughter. ll sceptical, I tried it on the "highest authority," r whom I happened to sit next day on committee. sighed "Yes. Many young men have generously ught bathing-dresses for their girl friends and are king forward to a revealing summer holiday. A dis- pointing time will be had by all—except the girl ends." Thus does English folk-lore keep in step with dern invention.

* * *

It is said that no two people see identical images of the me object. Do two newspapers ever make the same- ing of the same news? Take the Minister of Health's port for 1946, published last week. I saw that THE NCET, with customary sobriety, headed its summary Health and Disease in 1946." In the same strain the headline in a famous northern paper: "The tion's Health in 1946." Rather more risqué is the ption of our most famous London daily: "Better alth Figures." And this gaiety has also pervaded the ice of the leading Labour paper, which says: "Britain ays in Good Health." More ecstatically a London ening came out with "Nation was Never So Healthy," nile from Glasgow we have "Birth Rate at Record Level." But euphoria was not universal, for other papers announced: "More Deaths from Whooping-Cough" and "No Cure for Cold." At first I thought the best of all was: "281 Mothers who Need Not Have Died—Report of a Secret Inquiry": but the palm goes to the resourceful sub-editor who wrote: "We're Underfed and Getting Thinner, says Britain's M.O."

* * *

She was middle-aged and good-looking and kept a little business and her husband had left her. She shed no tear but her uterus began to bleed profusely and a crippling attack of lumbago laid her low. My gynæcological colleague, referring her to me, said that in his experience a sudden metrorrhagia of this kind was usually of emotional origin; and when I asked her about her other trouble, her first words were "it's like a stab in the back." Well, clinically she had no more than a prosaic prolapsed disc, but I think you will agree that her diagnosis was the right one. And how would you set about curing her?

* * *

How incalculable is the goodwill of our practices! A few mornings ago I was telling my not-so-ancient jobbing gardener of the illness of my wife and mentioned that I had called in young Dr. C, who had insisted that she be admitted forthwith to the nearest hospital. The not-so-ancient observed thoughtfully, "Ah! You wouldn't have known old Dr. C, would you, sir?" I replied that he was before my time and the not-so-ancient continued, "Ah! He was a grand doctor he was. Very clever he was, sir. If he said one of his patients wasn't going to get better he never did."

* * *

One of your peripatetic correspondents suggests the need for an Institute of Individual Research. For a long time now I have felt that there should be a Research Foundation for Criticism and Exposition. Its workers would agree to do no original investigations whatsoever. Their task would be to collect, correlate, and criticise (constructively one hopes) the original researches of others. The need for this is obvious since the volume of published facts and theories is growing with more than arithmetical progression. About 25 years ago I collected a bibliography of well over 3000 references to the physiology and pathology of the ovary. Many more additional papers must have accumulated since that time. It is almost impossible to read all the published work on even a small aspect of the medical field like this, and at the same time to carry out active research, clinical work, or teaching. The amazing thing is that many investigators manage to read so much. Personally I skim through a large number of journals and note a few titles which interest me. Of these I read the conclusions or summary of a few, and rarely I read a whole paper.

You may say that my demand is already met by the authors of textbooks, monographs, and reviews, but most of these are produced as a side-line to teaching or active experimental or clinical work. What I ask is that someone should finance carefully picked research-workers who could devote their whole time to constructive reviewing of a chosen field. The Fellows would be chosen from among those who can make vivid arrangements of essential facts but have no aptitude for experiment. The existing major research foundations would certainly turn down any applicant for a fellowship who proposed as his subject: "A critical review of the world literature on this or that."

* * *

I have decided to write a weekly paragraph on *What the Registrar is Wearing*, designed to keep job-hunters informed on this important aspect of medicine. Here is this week's instalment.

A tweedy montage is now the fashion in Harley Street, more or less in at the waist, with slight pectoral accentuation and an off-the-shoulder ceinture. A yard of rayon crêpe stitched inside the left cuff avoids the danger of losing a precious handkerchief and ensures permanent smartness. Collars should be stiff and white, offset by a grey (congenital or acquired) shirt; if there are several interviews a week paper collars can be worn and suitably disposed of according to the result of the interview. A double-breasted ensemble will be sure to impress, though for the pædiatric applicant an Eton-jacket may help.

Letters to the Editor

IMPROVEMENT OF THE NATIONAL DIET

SIR,—Since nobody else has taken up the points put forward by Dr. Leitner in his letter in your issue of May 22, perhaps you will permit me to do so. It is surely an astonishing fact that at the present time on the staffs of our hospitals there are no nutritionists recognised as such. We have no nutritional clinics, and apart from the occasional clinician who chooses to make it his special study, this vital subject might hardly be thought to figure in our practice at all.

This contrasts very strikingly with the situation in the United States. Picking up a number of the *Journal of the American Medical Association* at random—the issue of May 15—I notice that in a list of annual meetings of State medical societies two out of four have made nutrition the special subject for discussion. It might be understandable if in present circumstances our colleagues in the United States were to take the subject somewhat for granted, but it is scarcely credible that we who are beset incessantly by the problem should so consistently ignore it.

One result is that, as often as not, the public is led by the nose by the biochemists. Nutritional surveys are repeatedly undertaken on a basis of admirable biochemistry but only the most rudimentary clinical observation—which is hardly surprising in view of the fact that they are carried out not by doctors but by biochemists. Since it is only when malnutrition is severe that biochemistry is likely to prove informative, it is not surprising that the results of these surveys, and the widely publicised announcements based on them, so frequently arouse the derision of the practising clinician.

It is surely time that our hospitals, and especially our teaching hospitals, to whom we look as pioneers, reconsidered their responsibilities in the matter, and appointed nutritionists to their staffs. Nowadays the importance of nutrition as the foundation of health can hardly be exaggerated, and the subject grows apace in scope and complexity. The nutritionist has come to stay, and it is clearly essential that first of all he should be trained in medicine, and secondly that he should be a clinician of the highest possible standing and experience.

G. E. BREEN.

BACTERIOLOGICAL NOMENCLATURE

SIR,—From your leading article of June 19 it is clear that a generally acceptable nomenclature and classification of bacteria cannot be established yet. The existing confusion is due to a human tendency to see patterns, and to recognise genera and species on too few and incomplete data. You say that scientific names are now given to bacteria with the intention of making clear the relationship of one organism with another. Topley and Wilson[1] meant the same when they said: "The most promising *a priori* conception upon which to base a classification is the conception of species in a phylogenetic series."

My argument is that at the moment nobody can see clear in all this, and committee-work is no remedy. Phylogeny should start with the simplest characters—i.e., morphology. Here already too much is taken for granted. Bacteriology traditionally recognises spheres, rods, and spiral forms. The foundation of this fundamental *differentiation is continual observation* of dead, dried, fixed, and *stained* bacterial preparations—*in other* words, post-mortem work. Pathology had its origin in the post-mortem room; for morphological studies, its bacteriological branch still largely follows "morbid anatomy" methods. The electron microscope is a dangerous additional tool, and more and more artefacts are being studied.

Undeniably electron micrographs and methods of differential staining enrich knowledge of bacterial structure. The danger is that the resulting pictures are not usually interpreted from what can be made visible in live preparations, the reason being that live preparations of bacteria are rarely studied. Dark microscopy, the method of choice for this purpose, been abandoned by most workers through lack of suitable light source. For a number of years I have used (South African) sunlight, which is about the brightest light source available. As a result of examining thousands of preparations of live bacteria I have concluded that at least the motile "bacteria" are not rods, but spirals. During activity they present themselves as rotating, gyrating, undulating, spiral bodies and their cell walls are by no means rigid. A comparison with "spirillums" showed that there is little to choose between the living shapes of "bacteria" and "spirillums," except perhaps in length and amplitude of coils. Further observations convinced me that bacteria have no outside motor-organs, and that the wavy structures commonly called "flagella" are mucous twirls which occasionally peel off from the mucous coat through the very movement of the bacterial body.[2] A ciné-micrographic film (1400 ft) illustrating all this is available in Britain through Dr. W. E. van Heyningen, hon. secretary of the Society for General Microbiology, Sir William Dunn School of Pathology, Oxford. An abbreviated copy (750 ft), which may serve as an introduction to the subject, is with the Royal Microscopical Society.

Obviously, if my views are correct the difference between "bacteria" and "spiral forms" largely falls away, and "bacterial flagella" are no more. This would disturb fundamental conceptions of bacterial morphology, and a thorough revision of nomenclature and classification would become necessary. This brings me back to my starting-point—that efforts at bacteriological systematics are premature.

CARS FOR DOCTORS

SIR,—I am afraid Mr. Gresham Cooke's remarks have done little to brighten the prospect for those of us who have been nursing and cajoling ancient cars into a semblance of roadworthiness, while patiently waiting for the "really early date" at which the "high degree of preference" we enjoy would bring the new car.

Mr. Cooke will agree that a few instances of abuse must not be allowed to set the pace for the machinery whereby priority is given effect, and the present machinery is faulty partly because abuses are possible at all. If doctors are to accept some 4000 patients under contract with the Ministry of Health (would Mr. Cooke advise against this on the ground that—human nature being what it is—they might all decide to be ill at once?), efficient transport for doctors must be taken for granted, and the question of what constitutes a serviceable car for a doctor must be settled without delay and with precision.

I suggest that a "serviceable" car is the car Mr. Cooke would wish his own doctor to have when he needs him urgently—when for instance he has met with an accident and is bleeding from a severe head wound. Neither Mr. Cooke nor Mr. Bevan would accept the plea that the car only needs "a little attention" as an excuse for neglecting the call; nor would any doctor neglect it, although his job is made doubly anxious and difficult by an unreliable car. To wait until the car will not go at all, and will therefore pass muster as "unserviceable," is obviously fantastic. No-one needs a doctor with an unserviceable car, and the doctor would rightly be accused of negligence if he pretended to run a practice with it. He should be given every assistance in avoiding the catastrophe; and what help is he in fact getting?

He must have the formal sanction of the B.M.A. (so formal that it amounts to testifying that the doctor is a doctor), but he can only get this by first persuading the garage which normally handles his car that she is more trouble than she is worth. The garage provides a kind of "disability certificate" by which it implies that the car had better be replaced. In requesting the garage proprietor to give this, one is asking for no

meets the eye. and I rely on Mr. Cooke's knowledge
uman nature to know what it is. Very bluntly.
is asking the proprietor to deprive himself of a
ble source of income, while circumstances, Authority,
"nature", prompt him to keep it. This is far too
a responsibility for him (quite apart from any
ion he may have for his ever-ailing patient), even
he prophet enough to know at what point exactly
ar must be condemned in order to avoid disaster in,
ine months' time. Neither the length of the waiting-
or the probable state of the car at the end of it,
own to him, and he very sensibly postpones the
ard decision as long as he can. While constant
r repairs and occasional major ones will keep the
n the road an optimistic view of its performance
s appropriate, and the doctor can always hire one
e garage cars if his own breaks down completely.
e can; he can spend a small fortune on it. but the
ge proprietor is only showing common helpfulness
dertaking to keep a car on the road for the doctor
ll times. With the best will in the world, it is
ssible for him to decide where helpfulness ends,
a deplorable waste of time, money, and medical
iency begins. The doctor himself finds it difficult,
he knows what the car must be capable of in order
ake his work possible, and he bases his judgment on
he circumstances. It should not be necessary for
to send for help from the garage at 2 o'clock in the
ning in order to persuade the proprietor that a car
h will only start if one person presses the accelerator
e another cranks her up is not the right car for a
or. What then can he do, since his own opinion
e one that counts least. and the garage proprietor
either less human nor less fallible than himself?
an read about the high degree of preference and the
il trade's efforts to make deliveries really early—for
lucky chaps whose cars can in no way be described
erviceable.

hat, I fear, is virtually what Mr. Cooke has said,
it would be interesting to know how he would set
t caring for some 4000 people in a rural area where
all the roads are made, where hills are steep and
s scattered, while he awaited the requisite degree
ilapidation of his vehicle.

y all means let us avoid abuses of preferential treat-
t; but let us first give meaning to some of the
ds we rely on in deciding on preference and in explain-
what it entails. The country doctor with a large
ber of State patients must be assured an efficient
and the degree of priority to which his commit-
ts entitle him could be based on perfectly simple
ascertainable facts: how old is his present car;
many weeks of "absenteeism" are to be counted
inst it, and how much have repairs to it cost during the
t year? These are the facts which determine his
iency as a doctor, and these are the facts which should
e him on the manufacturers' waiting-lists. If still no
car were forthcoming, one would at least know that
ple in even greater need than oneself were getting it,
one would put up with the wastefulness of limping
g in the old one cheerfully enough. But to be
mped and frustrated by its hopeless inadequacy
the job, and to know that one must do it in the name
an economy which can neither recognise a valid claim
prevent abuse is quite insufferable.

he National Health Service places obligations on the
tor which force him to be possessed of the proper
ans for discharging them. The car is one of the
t, and the car must be one which will start when it
wanted, which will go where it is wanted, and which
l keep going until it has brought the doctor to the
t where he is needed. If there is reason to doubt the
idity of any doctor's claim, let an investigation be
de into the circumstances, such as area, number of
ients, and details (including cost) of repairs to his
sent car. An intelligent person can discover all
t is necessary within a few minutes, and he will
atly help economy generally by discouraging all those
o are in the habit of making futile claims. Nothing
solute is asked for from any responsible authority;
t an authority which meets valid and invalid alike
h meaningless commercialese like "really early date"
d "high degree of preference" is not a responsible authority—at least not to those who have waited in need for over six months.

If "very nearly the whole of the home quota for new cars" would be absorbed by the *needs* of the medical profession, then the home quota could hardly be put to better use.

WAITING-LIST.

SIR,—I have a copy of a recent letter from car manufacturers which says:

> "We would explain that we, as manufacturers, apportion the limited supply of new cars among our area distributors. The allocation of such cars to users is carried out by them, in conjunction with their dealers, who, with their local knowledge of individual cases, are in a much better position than we to judge orders which call for a measure of priority delivery, *quite apart, of course, from Government-sponsored medical priorities.*"

It would appear, therefore, that the term "preferential delivery" as stated by Mr. Cooke and Mr. Grafton in their letter of June 19, is intended to apply to those cases which do not come under the category of "Government-sponsored medical priorities." Perhaps Mr. Cooke can explain what is meant by this term.

Last year a motion was carried unanimously at the Panel Conference "pleading for effective priority for doctors in the supply of motor cars, the Government to be asked to insist that this priority be given by the manufacturers, if necessary, direct, and not through the usual agency channels."[1] Moreover, at this conference it was stated that there were "between 2000 and 3000 cases of urgency"; also that "technically in the list of priorities, doctors, nurses, and midwives were second only to the police, *but this did not work out in practice.*"

Is "the retail trade doing its best to advance delivery to a really early date" as suggested by Mr. Cooke?

Leeds. I. ROSE.

MULTIPLE LIVER ABSCESSES TREATED WITH PENICILLIN

SIR,—The case reported in your issue of June 19 by Dr. Seaward Morley is similar to one I described some time ago in a Hungarian journal.

A man, aged 44, gave a 3-days' history of rigors and fever; temp. 103°F with daily fluctuation of over 1°F. White blood-cell count normal; blood-sedimentation rate 70 mm. In the next 4 weeks the size of the liver gradually increased; the lower border—three fingerbreadths below the costal margin—became excessively painful, the tenderness extending to the right lumbal region. Slight icterus appeared; serum bilirubin 1·4 mg. per 100 ml. Penicillin was given, 100,000 units per day for 4 days; and for a short time the fever subsided. A week later 150,000 units daily was given for 5 days, without any noticeable effect. The fever persisted, with repeated rigors; and general condition became worse. Laparotomy (Prof. E. Hedri) disclosed multiple liver abscesses and the abdomen was closed. Penicillin therapy was reinstituted with 100,000 units per day for 3 days; on the 3rd day temperature became normal and the patient felt well. In consequence of our shortage of penicillin (this happened in March, 1946) we had to discontinue the injections; recovery was, however, swift and uneventful.

Though we gave only 300,000 units of penicillin as against 4,000,000 given by Morley, the fever disappeared in both patients on the 3rd day. In a case reported by Laspiur and Santamarina the temperature reached normal on the 3rd day, after 300,000 units of penicillin; but the injections were pursued to a total dosage of 1,200.000 units. A remarkable feature of our own case was the slight and transient effect of penicillin given before operation as compared with the complete and lasting result it had after exploratory laparatomy. Since in each case successfully treated with penicillin laparatomy has been performed, might it not be suggested that recovery is effected not by penicillin alone, but by giving penicillin (even in comparatively small doses) after opening the peritoneal cavity? The latter may contribute to improvement in a hitherto undetermined way.

If doctors are to accept* some 4000 patients under contract with the Ministry of Health (would Mr. Cooke advise against this on the ground that—human nature being what it is—they might *all* decide to be ill at once?), efficient transport for doctors must be taken for granted, and the question of what constitutes a serviceable car for a doctor must be settled without delay and with precision.

I suggest that a "serviceable" car is the car Mr. Cooke would wish his own doctor to have when he needs him urgently—when for instance he has met with an accident *and is bleeding from a severe head* wound. Neither Mr. Cooke nor Mr. Bevan would *accept* the plea that the car only needs "*a little attention*" as an excuse for *neglecting the call*; nor would any doctor neglect it, although his job is made doubly anxious and difficult by an unreliable car. To wait until the car will not run *at all*, and will therefore pass muster as "unserviceable" is obviously fantastic. No-one needs a doctor with an *unserviceable car*, and the doctor would rightly be accused of negligence if he pretended to run a practice with it. He should be given every assistance in avoiding the catastrophe; and what help is he in fact getting?

He must have the formal sanction of the B.M.A. (so formal that it amounts to testifying that the doctor is a doctor), but he *can only get this* by first persuading the garage which normally handles his car that she is more trouble than she is worth. The garage provides a kind of "disability certificate" by which it implies that the car had better be replaced. In requesting the garage proprietor to give this, one is asking for more

meets the eye. and I rely on Mr. Cooke's knowledge
uman nature to know what it is. Very bluntly,
is asking the proprietor to deprive himself of a
ble source of income, while circumstances, Authority,
"nature" prompt him to keep it. This is far too
y a responsibility for him (quite apart from any
tion he may have for his ever-ailing patient), even
he prophet enough to know at what point exactly
ar must be condemned in order to avoid disaster in,
nine months' time. Neither the length of the waiting-
nor the probable state of the car at the end of it,
nown to him, and he very sensibly postpones the
ward decision as long as he can. While constant
or repairs and occasional major ones will keep the
on the road an optimistic view of its performance
is appropriate. and the doctor can always hire one
ne garage cars if his own breaks down completely.
e can; he can spend a small fortune on it. but the
ge proprietor is only showing common helpfulness
ndertaking to keep a car on the road for the doctor
ll times. With the best will in the world, it is
ssible for him to decide where helpfulness ends.
a deplorable waste of time, money, and medical
iency begins. The doctor himself finds it difficult.
he knows what the car must be capable of in order
ake his work possible, and he bases his judgment on
he circumstances. It should not be necessary for
to send for help from the garage at 2 o'clock in the
ning in order to persuade the proprietor that a car
h will only start if one person presses the accelerator
e another cranks her up is not the right car for a
or. What then can he do. since his own opinion
e one that counts least. and the garage proprietor
either less human nor less fallible than himself?
an read about the high degree of preference and the
il trade's efforts to make deliveries really early—for
lucky chaps whose cars can in no way be described
erviceable.

hat, I fear, is virtually what Mr. Cooke has said,
it would be interesting to know how he would set
t *caring for some 4000 people in a rural area* where
all the roads are made, where hills are steep and
s scattered, while he awaited the requisite degree
ilapidation of his vehicle.

y all means let us avoid abuses of preferential treat-
t; but let us first give meaning to some of the
ds we rely on in deciding on preference and in explain-
what it entails. The country doctor with a large
ber of State patients must be assured an efficient
and the degree of priority to which his commit-
its entitle him could be based on perfectly simple
ascertainable facts: how old is his present car;
many weeks of "absenteeism" are to be counted
inst it, and how much have repairs to it cost during the
t year? These are the facts which determine his
iency as a doctor, and these are the facts which should
e him on the manufacturers' waiting-lists. If still no
car were forthcoming. one would at least know that
ple in even greater need than oneself were getting it.
one would put up with the wastefulness of limping
g in the old one cheerfully enough. But to be
mped and frustrated by its hopeless inadequacy
the job, and to know that one must do it in the name
n economy which can neither recognise a valid claim
prevent abuse is quite insufferable.

he National Health Service places *obligations* on the
tor which force him to be possessed of the proper
ans for discharging them. The car is one of the
t. and the car must be one which *will start* when it
wanted. which will go where it is wanted, and which
l keep going until it has brought the doctor to the
nt where he is needed. If there is reason to doubt the
idity of any doctor's claim, let an investigation be
de into the circumstances. such as area, number of
ients, and details (including cost) of repairs to his
sent car. An intelligent person can discover all
it is necessary within a few minutes, and he will
atly help economy generally by discouraging all those
o are in the habit of making futile claims. Nothing
solute is asked for from any responsible authority;
t an authority which meets valid and invalid alike
h meaningless commercialese like "really early date"
d "high degree of preference" is not a responsible authority—at least not to those who have waited in need for over six months.

If "very nearly the whole of the home quota for new cars" would be absorbed by the *needs* of the medical profession. then the home quota could hardly be put to better use.

WAITING-LIST.

SIR,—I have a copy of a recent letter from car manufacturers which says:

> "We would explain that we, as manufacturers, apportion the limited supply of new cars among our area distributors. The allocation of such cars to users is carried out by them. in conjunction with their dealers, who, with their local knowledge of individual cases. are in a much better position than we to judge orders which call for a measure of priority delivery, *quite apart, of course. from Government-sponsored medical priorities.*"

It would appear, therefore, that the term "preferential delivery" as stated by Mr. Cooke and Mr. Grafton in their letter of June 19. is intended to apply to those cases which do not come under the category of "Government-sponsored medical priorities." Perhaps Mr. Cooke can explain what is meant by this term.

Last year a motion was carried unanimously at the Panel Conference "pleading for effective priority for doctors in the supply of motor cars, the Government to be asked to insist that this priority be given by the manufacturers. if necessary, direct. and not through the usual agency channels."[1] Moreover. at this conference it was stated that there were "between 2000 and 3000 cases of urgency": also that "technically in the list of priorities. doctors. nurses, and midwives were second only to the police, *but this did not work out in practice.*"

Is "the retail trade doing its best to advance delivery to a really early date" as suggested by Mr. Cooke?

Leeds. I. ROSE.

MULTIPLE LIVER ABSCESSES TREATED WITH PENICILLIN

SIR,—The case reported in your issue of June 19 by Dr. Seaward Morley is similar to one I described some time ago in a Hungarian journal.

A man, aged 44. gave a 3-days' history of rigors and fever; temp. 103°F with daily fluctuation of over 1°F. White blood-cell count normal; blood-sedimentation rate 70 mm. In the next 4 weeks the size of the liver gradually increased; the lower border—three fingerbreadths below the costal margin—became excessively painful, the tenderness extending to the right lumbal region. Slight icterus appeared; serum bilirubin 1·4 mg. per 100 ml. Penicillin was given. 100,000 units per day for 4 days; and for a short time the fever subsided. A week later 150,000 units daily was given for 5 days. without any noticeable effect. The fever persisted. with repeated rigors; and general condition became worse. Laparotomy (Prof. E. Hedri) disclosed multiple liver abscesses and the abdomen was closed. Penicillin therapy was reinstituted with 100,000 units per day for 3 days; on the 3rd day temperature became normal and the patient felt well. In consequence of our shortage of penicillin (this happened in March, 1946) we had to discontinue the injections; recovery was, however, swift and uneventful.

Though we gave only 300,000 units of penicillin as against 4.000.000 given by Morley, the fever disappeared in both patients on the 3rd day. In a case reported by Laspiur and Santamarina the temperature reached normal on the 3rd day, after 300,000 units of penicillin; but the injections were pursued to a total dosage of 1200.000 units. A remarkable feature of our own case was the slight and transient effect of penicillin given before operation as compared with the complete and lasting result it had after exploratory laparatomy. Since in each case successfully treated with penicillin laparatomy has been performed, might it not be suggested that recovery is effected not by penicillin alone. but by giving penicillin (even in comparatively small doses) after opening the peritoneal cavity? The latter may contribute to improvement in a hitherto undetermined way.

Letters to the Editor

IMPROVEMENT OF THE NATIONAL DIET

SIR,—Since nobody else has taken up the points put forward by Dr. Leitner in his letter in your issue of May 22, perhaps you will permit me to do so. It is surely an astonishing fact that at the present time on the staffs of our hospitals there are no nutritionists recognised as such. We have no nutritional clinics, and apart from the occasional clinician who chooses to make it his special study, this vital subject might hardly be thought to figure in our practice at all.

This contrasts very strikingly with the situation in the United States. Picking up a number of the *Journal of the American Medical Association* at random—the issue of May 15—I notice that in a list of annual meetings of State medical societies two out of four have made nutrition the special subject for discussion. It might be understandable if in present circumstances our colleagues in the United States were to take the subject somewhat for granted, but it is scarcely credible that we who are beset incessantly by the problem should so consistently ignore it.

One result is that, as often as not, the public is led by the nose by the biochemists. Nutritional surveys are repeatedly undertaken on a basis of admirable biochemistry but only the most rudimentary clinical observation—which is hardly surprising in view of the fact that they are carried out not by doctors but by biochemists. Since it is only when malnutrition is severe that biochemistry is likely to prove informative, it is not surprising that the results of these surveys, and the widely publicised announcements based on them, so frequently arouse the derision of the practising clinician.

It is surely time that our hospitals, and especially our teaching hospitals, to whom we look as pioneers, reconsidered their responsibilities in the matter, and appointed nutritionists to their staffs. Nowadays the importance of nutrition as the foundation of health can hardly be exaggerated, and the subject grows apace in scope and complexity. The nutritionist has come to stay, and it is clearly essential that first of all he should be trained in medicine, and secondly that he should be a clinician of the highest possible standing and experience.

The *Medical Press*, 8, Henrietta Street, London, W.C.2.

BACTERIOLOGICAL NOMENCLATURE

SIR,—From your leading article of June 19 it is clear that a generally acceptable nomenclature and classification of bacteria cannot be established yet. The existing confusion is due to a human tendency to see patterns, and to recognise genera and species on too few and incomplete data. You say that scientific names are now given to bacteria with the intention of making clear the relationship of one organism with another. Topley and Wilson[1] meant the same when they said: "The most promising *a priori* conception upon which to base a classification is the conception of species in a phylogenetic series."

My argument is that at the moment nobody can see clear in all this, and committee-work is no remedy. Phylogeny should start with the simplest characters —i.e., morphology. Here already too much is taken for granted. Bacteriology traditionally recognises spheres, rods, and spiral forms. The foundation of this fundamental differentiation is continual observation of dead, dried, fixed, and stained bacterial preparations—in other words, post-mortem work. Pathology had its origin in the post-mortem room; for morphological studies, its bacteriological branch still largely follows "morbid anatomy" methods. The electron microscope is a dangerous additional tool, and more and more artefacts are being studied.

Undeniably electron micrographs and methods of differential staining enrich knowledge of bacterial structure. The danger is that the resulting pictures are not usually interpreted from what can be made visible in live preparations, the reason being that live preparations of bacteria are rarely studied. Darkgr microscopy, the method of choice for this purpose, been abandoned by most workers through lack of suitable light source. For a number of years I have used (South African) sunlight, which is about brightest light source available. As a result of examining thousands of preparations of live bacteria I h concluded that at least the motile "bacteria" are rods, but spirals. During activity they present th selves as rotating, gyrating, undulating, spiral bod and their cell walls are by no means rigid. A compar with "spirillums" showed that there is little choose between the living shapes of "bacteria" "spirillums," except perhaps in length and amplit of coils. Further observations convinced me th bacteria have no outside motor-organs, and that t wavy structures commonly called "flagella" are mucous twirls which occasionally peel off from t mucous coat through the very movement of the bacter body.[2] A ciné-micrographic film (1400 ft) illustrat all this is available in Britain through Dr. W. E. v Heyningen, hon. secretary of the Society for Gener Microbiology, Sir William Dunn School of Patholog Oxford. An abbreviated copy (750 ft), which ma serve as an introduction to the subject, is with t Royal Microscopical Society.

Obviously, if my views are correct the differen between "bacteria" and "spiral forms" largely fal away, and "bacterial flagella" are no more. This would disturb fundamental conceptions of bacterial morphology, and a thorough revision of nomenclature and classification would become necessary. This brings me back to my starting-point—that efforts at bacteriological systematics are premature.

Protoria, South Africa. University of Pretoria.

CARS FOR DOCTORS

SIR,—I am afraid Mr. Gresham Cooke's remarks h done little to brighten the prospect for those of us have been nursing and cajoling ancient cars into a semblance of roadworthiness, while patiently wa for the "really early date" at which the "high de of preference" we enjoy would bring the new car

Mr. Cooke will agree that a few instances of ab must not be allowed to set the pace for the machin whereby priority is given effect, and the pre machinery is faulty partly because abuses are poss at all. If doctors are to accept some 4000 patie under contract with the Ministry of Health (would M Cooke advise against this on the ground that—hum nature being what it is—they might all decide to be i at once?), efficient transport for doctors must be tak for granted, and the question of what constitutes a serviceable car for a doctor must be settled without dela and with precision.

I suggest that a "serviceable" car is the car Mr Cook would wish his own doctor to have when he needs him urgently—when for instance he has met with an accident and is bleeding from a severe head wound. Neith Mr. Cooke nor Mr. Bevan would accept the plea that th car only needs "a little attention" as an excuse f neglecting the call; nor would any doctor neglect i although his job is made doubly anxious and diffic by an unreliable car. To wait until the car will not r at all, and will therefore pass muster as "unserviceab is obviously fantastic. No-one needs a doctor with unserviceable car, and the doctor would rightly be accu of negligence if he pretended to run a practice with He should be given every assistance in avoiding t catastrophe; and what help is he in fact getting?

He must have the formal sanction of the B.M.A. (formal that it amounts to testifying that the doc is a doctor), but he can only get this by first persuad the garage which normally handles his car that she more trouble than she is worth. The garage prov a kind of "disability certificate" by which it imp that the car had better be replaced. In requesting t garage proprietor to give this, one is asking for m

SUPERANNUATION

R.—By now most doctors will have had a chance
udy the Ministry of Health's leaflet S.D.D.. containing
provisions by which practitioners holding life-
ance policies can "opt out" of the National Health
ice superannuation scheme. Many will have read
the excellent article by Mr. A. N. Dixon. manager
he Medical Insurance Agency. published in the
sh Medical Journal supplement of July 3, 1948.
hose who are still considering whether to enter the
rannuation scheme or rely on life-assurance policies.
ould point out that delay is inadvisable, since the
on will lapse on Oct. 4.

order to use this option a practitioner must have
in force on July 5, 1948. an endowment assurance
y. maturing not earlier than age 60. on which a
nium of at least £50 per annum is being paid. If
premium is less than £150 he must take out a further
y which will increase it to that figure or a higher one.
total premiums should be equivalent to approxi-
ly 14% of his anticipated net remuneration. for he
quired to contribute 6% per annum to which the
ster of Health will add 8%.

qualifying policy will not be acceptable. however.
is assigned to a third party. Many practitioners. I
w, possess substantial life-assurance policies, on
ch they are paying substantial premiums. but which
e been assigned to banks and others as collateral
rity for loans obtained for purchasing their practices.
n policies cannot be used to provide for their super-
uation—which is perhaps unfortunate. particularly
o many of these policies contain a provision whereby
could later be modified to endowment assurance
ch would meet the requirements of the National
lth Service (Superannuation) Regulations. They
be used only if the practitioner is able to secure
signment of the policy to himself before Oct. 4.
s should be clearly understood. for I feel sure that
rge number of practitioners who are intending to
on their life assurance will not qualify to do so
use of this restriction.

hat many will wish to opt out there is no doubt:
excellent though the superannuation scheme is. it
deficiencies at this stage which will be obvious.
icularly to a young practitioner with family responsi-
ies. Briefly. these deficiencies are: (*a*) inadequate
ision for the widow throughout, and during the first
years' service no provision whatever: (*b*) on retire-
t compulsory acceptance of a pension. though the
ment of capital would be far more acceptable in
y cases—e.g.. for a retiring practitioner in a poor
e of health. or for one who wants to live outside the
ted Kingdom income-tax area. A practitioner
ing on life assurance is able to counteract these
ciencies in the scheme. and the accompanying table
help those who are still undecided as to what they
uld do. In considering this table. it should be remembered that the life-assurance rates are those obtainable at present. and the pension quoted is the one that most leading life-assurance offices will be prepared to guarantee now. The comparison is based on equal contributions to the National Health Service scheme and to life assurance. In the case of life assurance I have assumed that a practitioner will take the obvious advantages of a "with profits" contract. and I have estimated the bonus conservatively.

The table illustrates the case of a doctor aged 35, with a wife of the same age. and an income (after deduction of expenses) of £1200 per annum. Under either scheme the total contribution is £168, of which he pays £72 and the Minister pays the remainder. Under the N.H.S. scheme he receives full tax relief on his share. but under the life-assurance scheme two-fifths' tax relief. The life-assurance policy is for £4500 with profits.

Years of service	N.H.S. scheme				Life assurance		
	Cash at death	Widow's pension	Cash at 65	Pension at 65	Cash at death	Cash at 65	Pension at 65
		(p.a.)		(p.a.)			(p.a.)
1 ..	£72	..	..	..	£4500	..	..
3 ..	£223	..	..	..	£4702	..	..
5 ..	£1200	..	..	..	£4837	..	..
10 ..	£180 +	£120	..	..	£5175	..	..
15 ..	£270 —	£120	..	..	£5512	..	..
20 ..	£360 —	£120	..	..	£5850	..	..
25 ..	£450 —	£150	..	..	£6187	..	..
30 ..	£540 —	£180	£540	£540	£6526	£540	£552

Under the N.H.S. scheme. if a practitioner dies after retirement. his widow will receive for the rest of her life one-third of his retirement pension: but this of course ceases immediately on her death. Under life assurance, on the other hand. pensions can be guaranteed for a fixed period. and a retiring practitioner could elect to accept a pension which would be guaranteed for 15 years. regardless of survivals. Unlike those we have previously considered. such a pension during the guaranteed period would not be subject to tax. and if accepted on this basis it would amount to £392 per annum. If the practitioner survived more than 15 years after retirement. this pension would continue to be payable during his life-time. but would attract income-tax after the guaranteed period had expired. If income-tax is assumed at the modest rate of 7*s.* in the £, a pension of £540 per annum will give the possessor £351 per annum. For the first 15 years, therefore. the practitioner would be financially better placed if he accepted the pension for the guaranteed period. If he died soon after retirement his widow would receive the full pension till the end of the 15 years, and in this way his capital would return to his estate.

I do not intend these observations to be construed as a recommendation to opt out of the N.H.S. superannuation scheme, but rather as a guide to practitioners who can fulfil the qualifying conditions and want to decide what is best suited to their circumstances. Many who do not at present qualify to opt out may find that it is not too late to modify their policies—e.g.. by altering the endowment period or by reassigning the policy—which will enable them to exercise free choice of method.

A. SHAW
Liverpool. Medical Agent and Medical Insurance Consultant.

THE editor of the *Medical Directory* writes: "To maintain the accuracy of our annual volume we rely upon the return of our schedule, which has been posted to each member of the medical profession. Should the schedule have been lost or mislaid we will gladly forward a duplicate upon request. The full names of the doctor should be sent for identification." The directory is published by Messrs. J. & A. Churchill, Ltd., 104. Gloucester Place, London, W.1.

PREVENTION OF PNEUMOCONIOSIS

SIR,—After perusing recent articles on pneumoconiosis one is again lost in wonder that no mention is made of the simple and sure means of prevention and protection—the use of a small light pad over the nose and mouth, as worn by nurses in the operating-theatre and children's wards. The pads are, of course, merely some six folds of butter-muslin or gauze, with tapes to tie behind the head, and could be provided in unlimited quantities, to be discarded after use.

By all means let us diminish or eliminate, as far as possible, the creation of dust and grit in trade processes and mining; but surely real prevention of anthracosis, silicosis, or any form of pneumoconiosis can only be obtained by providing exposed workers with a shield which will prevent any dust particles from gaining access to the respiratory system.

The director of the Pneumokoniosis Research Unit states that pneumoconiosis is a preventable disease, and calls for imperative administrative action. Is it too much to hope that such action might be directed towards preventing the condition, by the simple expedient suggested, rather than towards setting up a costly organisation to deal with the crippling and often fatal after-effects?

LEONARD HEARN
Senior Tuberculosis Officer
Nottingham. Notts C.C.

OPERATIONS FOR HERNIA

SIR,—In reading the interesting article of Moloney, Gill, and Barclay in your issue of July 10, I am reminded by their report of scrotal hæmatoma in 2 of the 230 cases discussed that this serious complication, with the almost inevitable sequel of infection, has not yet been eliminated from even the best of surgical practice.

Some of your readers may be interested in a simple bandaging procedure which I have used, with invariable success, during the past five or six years in all cases involving extensive separation of the cord and testicle from the scrotal wall.

At the close of the operation the incision is dressed, and the dependent part of the scrotum is picked up by an assistant between finger and thumb. A strip of elastic adhesive bandage about $1\frac{1}{2}$ in. wide and about 12 in. long is wound in spiral fashion around the scrotum from apex to base, obliterating the scrotal cavity by light and even compression (fig. 1), and so rendering the formation of a hæmatoma virtually impossible. The testes are thereby displaced towards the external inguinal rings. The spiral bandage must be retained in position by a strip of elastic adhesive bandage of similar dimensions extending from the perineum over the scrotum to the anterior abdominal wall (fig. 2). After three or four days the strapping may be released and a simple support substituted. The testicles soon regain their normal position.

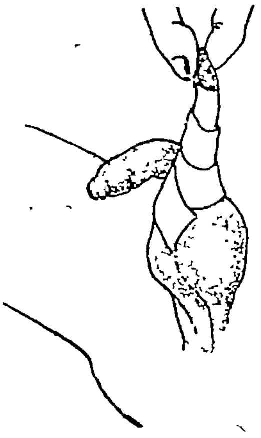

Fig. 1

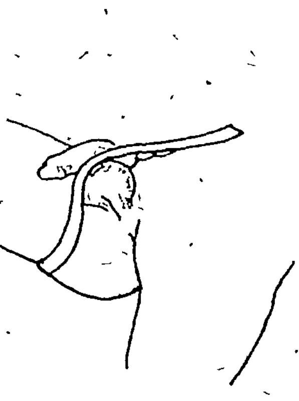

Fig. 2

Other methods have not proved satisfactory. For example, in one case in which the scrotum was stitched to the skin of the lower abdominal wall, the formation of a stitch abscess resulted in infection of the entire sc cavity.

I am indebted to Miss Barbara Duckworth for illustrations.

NORMAN GIBBON
Registrar to the surgical professorial u
Department of Surgery, University of Liverpool.

SIR,—The admirable article (July 10) by Mol and his colleagues on the nylon darn for hernia re an old method in a new look. Thirty years ago Sam Handley[1] described his darn and stay-lace method the radical cure of inguinal hernia. As one of his sur dressers I saw many of his cases, and the results w excellent. The material used was silk, and whilst th was occasional trouble from infection it was found t this could be avoided by soaking the silk in flav 1 in 1000, before use. The principles of the operati were the same as those now advocated—the avoidar of tension and of the displacement of normal structur The darn was used to strengthen the external obliq which Handley contended was often stretched a split, and for which no provision is made in the pre operation. The deeper layer of the darn in Molon operation was the stay-lace in Handley's and the latt seems a more appropriate name for it; perhaps sta laces are no longer in fashion in the new look.

London, W.1. E. W. RICHES.

PAIN

SIR,—In his interesting paper published on July 3, Dr. Keele rightly emphasised the value of pain as an aid to diagnosis, and in particular, he drew attentio to the help which may be gained from consideration of the time-intensity curve. It is agreed that in s conditions as angina pectoris, duodenal ulcer, thro angiitis obliterans, and some forms of sinusitis t information thus obtained is often enough to ena positive diagnosis to be made. Dr. Keele's views on he terms "psychogenic pain" may not, however m the same ready acceptance.

The term "psychogenic pain" is a bad one, be applied, as it often is, to a multiplicity of condi in which the diagnosis may be obscure. Further, ev pain is in a sense at least partly psychogenic, in that is a psychosomatic experience, the reaction to which determined not merely by the nature and severity of the pain but by all the related circumstances and particular by the general make-up of the individual concerned. As Leriche[2] has remarked, "Physical pain is not a simple fact of nervous impulses travelling over a nerve at a predetermined gait. It is the result of the conflict between the stimulus and the individual." Generally speaking, pain is not a prominent feature of purely neurotic states. The hysterical individual, fr from organic disease, who proclaims the agony of h pains in extravagant terms can hardly be regarded a suffering from pain in the generally accepted sense of the term when one views the happy mien of his coun tenance, or considers "la belle indifférence" with wh he accepts his misfortunes. In the anxiety state local cause for pains can generally be discovered: hea aches may be due to subconsciously maintained, persis scalp contraction; the low backache of many neuro women is only what one might expect from the droop posture they maintain; local muscular pains can re from prolonged tenseness; intestinal disorders are o the result of emotionally determined derangement function and so on. Pain, though appreciated central usually arises peripherally.

The extent of the reaction to all pain is determ by the factor of attention and by the emotional sta So it is that suggestible, neurotic patients may resp badly to the experience of pain and benefit tempora from purely psychological influences. Similarly, the s of a dentist's-chair may abolish the toothache of normally stable individual, even although the pa originates in an obviously carious tooth. For the reasons one should not attach too much diagnos

. ANEURIN BEVAN, Minister of Health, said that e case of any drug there would always be a time-)etween its discovery, its announcement to the ɔal press and to scientists generally, and its pro-)n and use throughout the whole health system. s most undesirable that where that inevitable time- ok place there should be sensational propaganda st the administration alleging that people were because it was not available and at the same time ıg false hopes and fears in the breasts of those were most concerned about individual cases. It)erfectly true that the use of streptomycin was still early stages, and it had to be used carefully because toxic effect. It was also desirable that it should ɜed under hospital conditions and preferably with atory controls. It was, however, a fact, now lished by the Medical Research Council, that culous meningitis did react in some instances ırably to the use of streptomycin. It was not yet n in all these cases, until sufficient time had elapsed, her there would be a relapse. But in about 31% e cases hopeful results had been realised. During investigations quite naturally the therapeutic f streptomycin was restricted. That was inevitable it had been found to be safe to use it clinically. that it was established, however, that streptomycin efficacious to some extent both for tuberculous ngitis and miliary tuberculosis, arrangements were ; made to provide treatment for as many cases as ble of these conditions. These arrangements would apply if the value of streptomycin was reliably n in other cases. There were known to be a number ther borderline conditions where streptomycin 't be efficacious, and the developments were therefore ; on. The supply was being planned and British uction increased to meet all these needs.

l the regional boards, Mr. Bevan stated, had been l to say at what hospitals and sanatoria, with uate staff and facilities, these cases were or could be ght together. Twenty-six such treatment centres already been provided. As soon as the information available as to where additional centres were to be lished, supplies of streptomycin would be provided them. Arrangements had been made to supply tomycin for cases in other hospitals if there was ed for them in a recognised centre. A doctor at hospital could get streptomycin for these types of by applying to the Ministry of Health supplies on.[1] From July 14 to 19 1150 grammes of strepto- ı had been supplied in response to 25 requests of ind.

nical trials now suggested that cases of tracheo- chial tuberculosis should be brought within the ment scheme. Regional hospital boards had there- been asked to say which hospitals should receive lies of streptomycin for this purpose. An expert cal committee was being set up to advise what other s of case should, in the light of clinical trials, be ght within the scheme, and arrangements would be ıded on the basis of their advice. It was estimated in order to treat all cases of miliary tuberculosis, rculous meningitis, and tracheobronchial tuberculosis ıe country, not more than 40 kg. of streptomycin d be needed every month.

om November, 1946, until now, including 50 kg. h was arriving in August, 300 kg. of streptomycin been imported from the United States, at the cost of)00 dollars. A further 50 kg. was on order. Large- production of streptomycin in this country was beginning. On May 8, firms engaged in this work asked to take all possible steps to speed up progress, eport difficulties, and to ask for any help needed in ing plant and raw materials. It was expected that tal of 25 kg. would be received (packed, tested, and y for use) this month and at least 50 kg. in August. luction should reach 100 kg. a month by the autumn. ırther plant with a much larger capacity should come operation early next year. These supplies would e than meet the needs of all cases where the use of ptomycin was so far recommended, and would enable tment to be extended to other types of cases as expert ice favoured it.

Bread Rationing

On July 21, Mr. JOHN STRACHEY, Minister of Food, informed the House of Commons that the present system of bread and flour rationing, together with the restrictions on the serving of bread in restaurants, would end on Sunday, July 25. Even today, he said, the quantity of wheat available in the world, and our own ability to command the foreign currencies necessary to purchase it, were strictly limited. Hence the Government did not now propose to return to the unrestricted sale of bread and flour for any purpose—whether for human or for animal consumption—which the purchaser might choose. The delivery of flour from mills would be controlled administratively by the Ministry in such a way as to keep the rate of offtake from July 18 at approximately the same level as during the previous twelve months. There could be no justification for the use of bread or flour for feeding livestock; and to assist the retailer in preventing the purchase of flour by his customers for this purpose the purchase or sale of more than 28 lb. of flour by retail at any one transaction would be forbidden. Very appreciable savings had been made in the first year of bread rationing, which was the most critical period; there was little doubt that without rationing we should have suffered a breakdown in the supply of bread to the population in April or May, 1947. Even in the second year, when rationing was probably having little effect on the level of human consumption, it still served to limit the feeding of bread and flour to animals. The total offtake remained, on average, between 1000 and 2000 tons a week below the pre-rationing level.

QUESTION TIME

Private Patients and N.H.S. Medicines

Sir ERNEST GRAHAM-LITTLE asked the Minister of Health why patients of doctors who remained outside the National Health Service were debarred from receiving free medicines, although eligible for free treatment in hospital; and whether, in the case of those patients who had paid the full contributions under the National Insurance Act, 1946, including the contribution in respect of the health services, and had also paid that part of the cost of health services derived from taxation, he would include free provision of medicines as well as of hospital services to patients of doctors not participating in the National Health Service—Mr. BEVAN replied: The diagnosis of what is needed, its prescription, and its provision, must be treated as part of one process. I could not justify separating the prescription from the medicine in this way.

Doctors in Rural Areas

Major TUFTON BEAMISH asked the Minister of Health whether he was aware that owing to the fact that no travelling allowances were paid to doctors for visiting patients in their homes, doctors in rural districts were obliged to refuse registrations from persons living more than a short distance from their surgeries; and whether he would take steps to prevent the health of the rural community suffering in this way.—Mr. BEVAN replied: Special payments (the details of which are under discussion with the British Medical Association) will be made to meet such cases. There is no financial justification for a doctor to refuse a patient in the circumstances described.

Doctors' Remuneration

Dr. SANTO JEGER asked the Minister whether he was aware that many doctors who had joined the National Health Service were in serious financial difficulties because their income from private patients had largely ceased, their panel cheques paid early this quarter had been exhausted by their regular commitments, and they had no current money to meet day-to-day expenses; and whether he would therefore arrange for doctors to receive interim payments, on account of their basic salary or otherwise, to bridge the interval until their next regular payments were due.—Mr. BEVAN replied: I do not think there can be many such cases, but I am proposing to arrange for advances to be made in cases of special hardship.

N.H.S. and Drugs and Appliances

Mr. H. E. RANDALL asked the Minister of Health if doctors, under the new health service, would be free to prescribe for the patients, without restriction, every kind of drug and appliance necessary for their treatment and would not have

Medicine and the Law

Alleged Neglect of Mental Defective

Several doctors gave evidence, some of it conflicting, at the Hertfordshire Quarter Sessions, on July 12, when Miss G. E. Sherwood, a children's nurse, aged 60, who keeps a home at Potters Bar for mentally retarded children, was accused of neglecting an 8-year-old boy in a manner likely to cause him unnecessary suffering or injury. She pleaded not guilty.

Mr. W. D. Bedford, surgeon to Hertford County Hospital, said that when he examined the boy in the hospital after his removal from the home he found him to be extremely wasted and emaciated, and suffering from tuberculous peritonitis caused by starvation.

Dr. Joseph Dwyer said he had examined the child some time before he went into the home, and found him fit, apart from congenital heart disease. On March 5 last, in answer to a request from the child's mother he telephoned Miss Sherwood that he would like to examine him again, but she would not permit it, as she had her own doctor. He later examined the boy in his own home, and finding alarming emaciation with a huge abdomen he suspected tuberculous peritonitis. The child's skin was dirty yellow, with fine powdery scales, indicating, Dr. Dwyer said, that he was suffering from a shortage of vitamins. Numerous ecchymoses on the legs were attributable not to any injury but to his condition. He thought the boy would not have survived another six weeks at that rate. His weight was then 28 lb. After removal from the home his weight rose by March 20 to 40 lb. In his opinion the emaciated condition was due to malnutrition from deprivation of food. He did not think that the shape of the boy's head indicated that he had had rickets.

Dr. J. R. F. Innes, house-surgeon at Hertford County Hospital, said the boy was put to bed when admitted to the wards. Radiography revealed no sign of organic disease. He was not given any specific treatment, but vitamins, fresh food, and fresh air, to which he responded well. The distension of the stomach subsided.

Mr. King-Annington, defending counsel, asked the jury why a woman who had spent fourteen years as a nurse for mentally retarded children, should deliberately starve this child. What was her motive? It was to her interest to look after him. The prosecution said the child was starved of food. The defence was that he was given the food and ate voraciously, but that he was unable to derive the benefit from his food which a normal child would have done. There was a family history of diabetes, of which his father had died, and his mental defect was associated with metabolic disturbance and breakdown in assimilation. The fact that he had dropped weight did not mean that he was starved. There was also the factor of emotional disturbance.

Miss Sherwood, in her evidence, said that in her home there were seven other children, and none of their parents had withdrawn them. When the boy came to her he was very thin in the limbs, and his hands were like claws. He was seen by a doctor every month. His right eye was discharging and he had catarrh. She denied starving him, and said that on the contrary had done her best for him.

Dr. A. F. Tredgold, who had examined the boy on July 6, put him in a low-grade mental category; he could understand only a few simple requests and his speech was limited to a few words. His stature and state of nourishment were below that of a normal child of his age. The skull was square and irregular and bossed and suggested that at some time he had had a mild attack of rickets. Asked if the boy's condition suggested that he had been starved, Dr. Tredgold replied that it depended on the way the word starvation was used; if in the popular sense, as meaning the withholding of food, then he would say no; but if in the medical sense, as meaning the inability of the tissues to absorb food, he would say yes. In his opinion the loss of weight was due primarily to the condition of the brain, with the condition of the heart as a secondary factor. He had spent some time in the home and formed the impression that Miss Sherwood was kind-hearted and devoted to the welfare of the children and anxious to do all she could for them and their mental develop- The other seven children appeared well cared for

The chairman of the magistrates said there three possible reasons for the boy's condition: (1) t he was not given sufficient food; (2) that he suff from tuberculous peritonitis; and (3) that owing defective metabolism he was unable to assimilate food. He asked whether Dr. Tredgold thought (3) likely than the others. Dr. Tredgold replied "Not likely, but the only one." Quoting from the section low-grade mental patients in his own textbook he out: "Assimilation was so defective that in spite of abundance of food they remained stunted and un nourished." Dr. Ernest Taylor, medical superinten of Middlesex Colney, agreed with the evidence given Dr. Tredgold.

Dr. J. Dalziel, the doctor who attended the b once a month, said that Miss Sherwood had drawn attention to the fact that the boy was thin and he recommended that he be given extra sugar; his app was good. He had found Miss Sherwood exceptional conscientious, and if he had a child he would have hesitation in sending it to her home.

The Chairman said the child was in a serious conditi and asked Dr. Dalziel whether he considered the respon sibility lay with him or Miss Sherwood. Dr. Dal said he accepted responsibility in the light of events.

Dr. William Horner, of Surrey, said that a grands was in Miss Sherwood's home and he was quite satisfied with the boy's condition and treatment. The child's father was also a doctor. Mr. Richard Harrison, an author, had volunteered to give evidence because he had a son in a similar condition. Last September he had the child taken to an institution, and after a week there was deterioration and loss of weight. He was informed that it was due to the new environment and that the child would pick up when it adjusted its The child was scarcely able to stand or walk. It h received every care and plenty of food, but still contin to lose weight.

After a hearing lasting two days, the jury fo verdict of guilty, and Miss Sherwood was senten one day's imprisonment. Notice of appeal has been

Parliament

Steptomycin Supplies to Hospitals

In the House of Commons on July 21 Mr. S. T. Swingler called attention to a case in which a doct at the Staffordshire Infirmary, who applied urge to the Ministry of Health for a supply of streptomyc for the treatment of a young girl suffering from tub culous meningitis, was refused on the ground that t Staffordshire Infirmary was not one of the hosp authorised to have a supply of the drug under the Med Research Council. The patient, it was stated, must sent to the nearest authorised hospital—namely, t Queen Elizabeth Hospital in Birmingham—but o inquiry there he was informed that, though there a supply of streptomycin, there were no vacant be The girl's parents and the hospital authorities t appealed to Mr. Swingler for assistance, and on app tion to the Emergency Bed Service in London he w told that there were no immediate vacancies in of the hospitals which had streptomycin and that t fore it was a question of waiting. After 24 h discussion the Minister of Health authorised the s of streptomycin to Staffordshire Infirmary. For those concerned were very grateful. At the same t a private gift of streptomycin was received from ab from a generous American. While making no crit whatever of the N.H.S., because the problem before its inauguration, Mr. Swingler urged that kind of administration must be flexible and fast-mo where urgent cases were concerned.

Colonel M. Stoddart-Scott asked the Minister to whether streptomycin was now the acknowledged tr ment for tubercular meningitis. About two y ago the Minister discouraged its use in this country it had passed through *certain* tests. Had those t proved satisfactory, and did the Minister not recomm its use wherever possible?

Notes and News

STREPTOMYCIN

e House of Commons last week, as reported in our entary column, Mr. Aneurin Bevan said that supplies tomycin are now obtainable from the Ministry of for the treatment of miliary tuberculosis and tuber- eningitis. Between 8.30 A.M. and 6 P.M. on weekdays 1 8.30 A.M. and 2 P.M. on Saturdays) the telephone for such applications is KENsington 3471 (extension t all other times (night and weekends) the number is all 4300.

PAY OF STUDENT NURSES

s last meeting the Nurses Salaries Committee, which ised the Minister of Health since 1942, recommended pay of student nurses should be increased by £15. nister has accepted this recommendation and the will have effect from July 5. Student nurses from t London hospitals on July 23 sent a letter to the and to the General Nursing Council asking if a on could meet representatives of the Ministry to the whole question of their salaries. They consider increase is insufficient as they will now pay £18 a National Insurance. At a meeting of 800 nurses held Royal College of Nursing on the same evening (*Times*,) it was explained that the proper procedure now e for the nurses to register their complaints through dent Nurses' Association, when their proposals would with by the Whitley Council for midwives and nurses, eld its first meeting on July 21.

HELP FOR ALCOHOLICS

HOLICS Anonymous, the society run by recovered es to help others to overcome alcoholism, has often ntioned in our columns. On July 15 a public meeting d by members of the London group of the society, at members and their friends, about twenty doctors, and s of the press were present.

Marty Mann, executive director of the American l Committee for Education on Alcoholism, and one of three U.S. government delegates to the Inter- l Congress on Alcoholism, at Lucerne, told how, nine go, the society was able to help her to recover from alcoholism. After five years of sobriety she con- he idea of the national committee, of which she is the It was launched under the sponsorship of Yale Univer- 1944, as part of the Yale "plan on alcoholism." In n to the committee this plan covers publications (such nal studies, monographs, research projects, and ets), a summer school on alcoholic studies, and a or diagnosis, treatment, and research. The com- task is to teach the general public that alcoholism is e, and the alcoholic a sick person who can be helped worth helping; and that—in America, at all events— sm is a public-health problem and therefore should be ic responsibility. Mrs. Mann has lectured to non- es in cities and towns all over the United States and re, and has been responsible for starting many local tees. It is not unusual, it seems, after she has lec- n a city for the membership of the local Alcoholics nous group to double or even treble. Alcoholics of years' standing, who have been unwilling to admit ndition, find the courage to join the society and to y its help.

ERNATIONAL POLIOMYELITIS CONFERENCE

First International Conference on Poliomyelitis, held York this month, was attended by some 2000 delegates; the words of a *Times* correspondent (July 22), though olutionary discoveries were announced, "much dead- n research at all stages was cleared away." The theory e diversity in epidemiology is due to a change in the host rather than in the virus was again voiced by Albert B. Sabin, of Cincinnati, who suggests that the ce in resistance between different peoples is due to variations in environment. A call for better organisa- d more careful selection of treatment was made by L J. Seddon, who pointed out that there seems to be ntific justification for most of the preventive measures o control outbreaks. Quarantine, he said, has a ive effect on community life and

lost out of proportion to its possible benefit. He favours only the most obvious measures of prevention, which should be organised by a "general staff." Another delegate advocated an educational programme directed at the community in general and not simply at those with the disease in the family. As things stand, families develop a feeling of responsibility for the illness, and there is also great stress when the child returns home after months in an institution; some 38% of the cases investigated exhibited behaviour problems on returning home. Experimentally, Dr. Isabel Morgan, assistant professor of epidemiology at Johns Hopkins University, has obtained complete immunity in a high percentage of rhesus monkeys injected intramuscularly with a live virus of Lansing and Brunhilde strains. Protection, says the *Times* report, was achieved by overproduction of antibodies, which caused them to "spill over" into the central nervous system. The administration of pentnucleotide and yeast nucleic acid has been found to protect up to 90% of mice exposed to experimental infection. At the Philadelphia Children's Hospital there have been trials of oxythiamine, an analogue of thiamine and nitrous acid, which produces a deficiency of vitamin B_1; in mice its administration produced an almost immediate increase in resistance to the virus.

University of Manchester

The following appointments are announced:

Dr. H. T. Howat, lecturer in medicine; Dr. H. J. Wade, hon. clinical lecturer in medicine; Dr. G. G. E. Smyth, lecturer in medical neurology; Mr. H. P. Lawson, lecturer in otolaryngology; Dr. A. Holzel, lecturer in child health; Dr. Fred Stratton, special lecturer in human serology; Dr. Harold Jackson, hon. lecturer in experimental and radiation therapeutics; Dr. H. S. Barber, assistant clinical director of chronic rheumatism research centre; Dr. Oscar Janns, chief assistant in chronic rheumatism research centre; Dr. J. S. Lawrence, physician in charge of rheumatism research clinic; and Mr. F. H. Scotson, clinical lecturer in surgery for dental students.

Royal College of Physicians of Edinburgh

At a meeting of the college on July 20, with Dr. W. D. D. Small, the president, in the chair, Dr. D. R. Maitland and Dr. E. K. Morris were introduced and took their seats as fellows.

The following elections were made:

Fellows.—J. Laurie, W. M. Wilson.

Members.—D. R. MacCalman, J. G. A. Davel, H. D. Jenner, J. Sandilands, I. C. Gilliland, E. M. Donaldson, P. W. Hannay, V. V. Shah, J. Green, J. S. Theron, R. W. Biagi, D. I. McCallum, T. Parkin, A. R. Wilson, A. A. C. Ross, Amy Jungalwalla, D. M. Forsyth, N. C. Begg, D. S. Harling, R. G. Mathers, E. V. B. Morton, J. K. Scott, J. A. Tulloch, D. Naidoo, J. A. Morton, D. Banerji, T. W. G. Kinnear, A. M. Kassim, C. F. Rolland, A. C. Arthur, H. D. Ritchken.

Royal College of Obstetricians and Gynæcologists

At a meeting of the council held on July 24, with Sir William Gilliatt, the president, in the chair, the following officers were re-elected: president, Sir William Gilliatt; vice-presidents, Sir William Fletcher Shaw, Mr. J. M. Wyatt; treasurer, Mr. A. A. Gemmell; hon. secretary, Mr. H. G. E. Arthure; librarian, Mr. F. W. Roques; curator of the museum, Mr. Aleck Bourne.

The following were admitted to the fellowship:

Francis Richard William Kinkead Allen, James Bruce Dewar, Peter Joseph Kearns, Hector Ross MacLennan, George Randolphe Sparrow.

The following were admitted to the membership:

S. G. Aitken, Islay C. Barne, Wallace Barr, Fred Benjamin A. B. Higginson.

The following were elected to the membership:

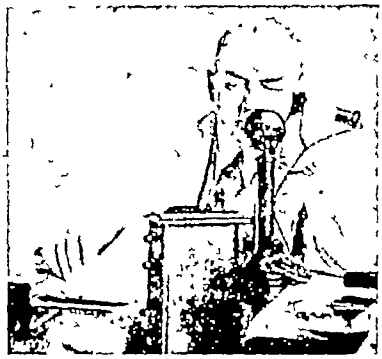
T. M. Abbas, I. S. R. Bain, Henrietta E. Banting, T. L. S. Baynes, Samuel Behrman, D. C. A. Bevis, C. C. Bowley, T. St. V. W. Buss, L. W. Cox, T. E. Elliot, P. M. Naidu, Mary E. Egerton, Margaret Fitzherbert, G. McI. Forsyth, H. D. Freeth, G. B. Gibson, J. H. Gibson, Andrew Graham, A. H. Grenz, Constance A. Grey, H. B. Hattam, C. C. Henneberg, Ebbie Hesselberg, D. W. Higson, J. C. Holman, K. R. Hudson, A. G. Jones, J. B. Joyce, R. A. Irani, W. T. Kenny, G. G. Kerster, R. A. H. Kinch, Samuel Lask, T. L. T. Lewis, Ethna W. Little, E. L. F. McConnachie, William Macfarlane, J. M. McKiddie, S. H. Madden, Helen M. Mayer, G. W. H. Millington, F. L. E. Musgrove, C. G. Nairn, J. R. Norris, J. J. F. O'Sullivan, J. H. Patterson, A. C. Pearson, W. H. Peek, S. D. Perchard, David Prysor-Jones, M. S. Qureshi, E. H. Rees, S. McR. Reid, H. A. Ripman, D. N. S. Robertson, Helen M. Russell, B. W. Sanderson, Humara Sayeed, S. A. Siddiki, G. A. Silley, A. A. Smith, Tom Smith, G. J. Sophian, Christine M. Stacey, P. C. Steptoe, C. S. N. Swan, R. A. Thatcher, G. S. Thomas, R. G. Whitelaw, P. de S. Wijesekera, R. M. Williams,

to work within the limits of averages of cost per insured person.—Mr. BEVAN replied: A doctor has a duty to prescribe under the National Health Service all drugs necessary for the proper treatment of the patient without any limit of cost whatever, also the appliances prescribed in the General Medical and Pharmaceutical Regulations. Other appliances are obtained through the hospital service.

Obituary

THE LATE DR. GOODHART

I. B. M. writes: G. W. Goodhart was essentially a clinician at heart and was one of the early band of clinical pathologists who took pathology to the bedside, although, as he himself has said, "clinical describes not the place where the investigation is made, but the purpose that is in view in making it." It can be said that in more senses than one he was a direct descendant of the Guy's physicians of the older school. He was not, in the strict sense of the word, a scientist; rather had he a fund of clinical sense, and common sense. It was this that made his opinions so valuable to his colleagues, maintaining as he did that "pathology is and must remain the rock on which the house of medicine is built." His loyalty to those who had been his seniors, and to his juniors—the latter one of his most striking characteristics—inspired complete confidence and very real affection. There can be no doubt that the large measure of success that the L.C.C. pathological services have achieved has been due to the careful selection of the first group pathologists of whom Goodhart was one; and those of us who worked in his department owe him a great debt. He was fond of talking and although one learnt the wisdom of allowing more time for a conversation with Goodhart than with most people, the time spent was never wasted, and one never left him without feeling the benefit of his wisdom and being refreshed by his humour. Very rarely did he say anything derogatory about anyone; he had the habit of finding and praising good points which others might have missed. His easy-going geniality made him very approachable, and he had the knack of making imagined trouble or disaster mere trivialities. His first few words would minimise them and put them in the right perspective. At the same time he went straight for essentials, and he knew what was fundamentally important and what was not. To say that he was easy-going is not to belittle him: humbug and deception he spotted at once and dealt with severely if need be. His laboratory was not complete without his own cheery figure and warm-hearted smile, and his juniors felt as if they were guests there; in consequence he got the respect he deserved, and the happy atmosphere which was so apparent was due to the fact that his assistants worked well because they liked working for him.



His philosophical fortitude during his illness did not surprise those who knew him well. He realised how ill he was and the inevitable outcome, but his spirit never left him; rather did it seem enhanced. His characteristic courage was never better seen than in his presence at a Guy's Club dinner a little more than a month before his death. He was devoted to his family and by them and his many friends he will be sadly missed. Those of us who have been fortunate enough to know him well and to work with him cannot but feel his influence now and always. It is to be hoped that the type of Christian gentleman personified by G. W. Goodhart will still be found among the rising generation in this materialistic age.

FARQUHAR McGILLIVRAY LOUGHNANE

F.R.C.S.

Mr. Farquhar Loughnane, surgeon to All S Hospital and consulting urologist to the London Co Council, died in London on July 14 at the age of 6

He was educated at Clapham College, King's Co London, and St. Thomas's Hospital, where he entrance and Peacock scholarships and won the trea gold medal. In 1912 he obtained the Conjoint qual tion and two years later the F.R.C.S. After ho resident appointments at St. Thomas's, the Royal Bathing Hospital, Margate, and Camberwell Infir and also at Salford and Leicester, he served as a sur with the British Red Cross in France, and later with R.A.M.C. as a surgeon specialist in Mesopotamia

Besides his appointment at All Saints, Lou was assistant urologist at the Prince of Wales's Hos Tottenham, and surgeon to St. Mary's Hospital, Plais To this last hospital, where he had worked for 25 ye he was especially generous of his time and thou serving on the board of governors and on many co mittees. With his background of war experience had wide surgical interests, and he had written on diverse topics as spinal tuberculosis and frost-b but it is as a urologist that he will be chiefly remember His *Handbook on Renal Surgery* appeared in 1926, a he published many papers on different aspects of h specialty, notably genital tuberculosis and prostatectom

W. P. G., a colleague at Bethnal Green Hospital where Loughnane was appointed consulting urologist in 1933, writes: "As a cystoscopist and intravesical instrumentalist, he was seen at his best; the speed and precision whereby he could remove a prostate with the resectoscope, was a revelation. To his juniors he w kindness itself: it was always the youngest memb of the team who passed the cystoscope for him, and h went to great pains to demonstrate cystoscopic app ances to junior nurses. After the weekly clinic ca the inevitable cup of tea and the informal conference, at which he would come under a barrage of questions. He was not easily know once his confidence had been gained he prov a delightful friend and agreeable colleague. I young days he had been a keen golfer, but toward end he got caught up in that most enthralling of h —restoration of old country cottages. He liked spend his spare moments at his home on the Ke coast among the country folk and fishermen he k so well."

He was married in 1927 and Mrs. Loughnane surv him.

Births, Marriages, and Deaths

BIRTHS

ASQUITH.—On July 19, the wife of Dr. Raymond Asquith—
COLLIE.—On July 21, in London, the wife of Dr. Ian Collie—
FRYER.—On June 19, at Hillingdon, the wife of Dr. Graham —a son.
HEATHFIELD.—On July 22, at Chingford, Essex, the wife of K. W. G. Heathfield—a son.
KERR.—On July 17, at Dumfries, the wife of Dr. P. M. Kerr —a son.
LAING.—On July 22, at Limpsfield, Surrey, the wife of Dr. Laing—a son.
LLOYD.—On July 17, at Tenterden, the wife of Dr. T. W. —a daughter.
MANN.—On July 16, in London, the wife of Dr. —a son.
MAXWELL-MULLER.—On July 20, at Molesey, the wife of Dr. Maxwell-Muller—a daughter.
PORRITT.—On July 19, in London, the wife of Mr. A. E. F.R.C.S.—a daughter.
ROBINSON.—On July 18, at Sheffield, the wife of Mr. R. G. O.M., F.R.C.S.—a daughter.

MARRIAGES

CROSSKEY—CROUCH.—On July 17, at Warwick, Henry Crosskey, M.B., to Katherine Sheila Mildred Crouch,
MOSS—TOOKE.—On July 17, at Ealing, Hugh James Moss, to Jean Veronica Tooke.

DEATHS

FULLER.—On July 10, at Perranporth, Cornwall, Andrew Fuller, M.R.C.S., D.P.H., aged 55.
McGOWAN.—On July 24, at Oldham, James Sinclair M.D. B.SC., Lond., aged 81.
OWEN.—On July 21, Emrys Daniel Owen, M.B. B.SC., Wale
SCOTT.—On July 16, at Longside, Aberdeenshire, William Gordon Scott, L.R.C.P.E., aged 67.

:RHOSIS OF THE LIVER IN CEYLON AND ITS RELATION TO DIET

A REVIEW OF 102 CASES

P. B. FERNANDO
M.B. Lond., M.R.C.P., D.T.M. & H.

O. R. MEDONZA
L.M. & S. Ceylon

P. K. RAJASURIYA
L.M. & S. Ceylon

From the Department of Medicine, University of Ceylon

HE wide prevalence of cirrhosis of the liver in tropical tries has been noted by many workers. Its causation pathogenesis, however, have remained obscure. diseases have been suggested as of ætiological tance, such as amœbic dysentery (Rogers and w 1946), bacillary dysentery (Menon and Annamalai , and malaria (Hughes 1933), but these are so present without the supervention of cirrhosis that other factor too seems to be involved. Alcohol, h is an important ætiological agent in Europe and rica, is comparatively infrequent as a cause of liver osis in the tropics. The experimental production of al cirrhosis in animals by diet alone (Himsworth and n 1944) suggests that the common factor in many cal conditions favouring the development of cirrhosis be deficiencies of diet. Dietetic deficiencies are spread in certain tropical countries where cirrhosis mmon, and cirrhosis has been produced in animals tained on certain of these diets (Gillman 1944). her studies correlating the clinical types of cirrhosis the underlying diets are necessary before the ætio- al rôle of diet in the production of cirrhosis is blished. The clinical histories of 102 patients treated s for cirrhosis have been studied from this point of .

e following figures give an idea of the prevalence of osis in Ceylon :

The average annual death-rate from cirrhosis of the in Colombo, where the registration of death is by qualified cal men, for 1941–46 was 13·6 per 100,000 of the lation.

During the same period the average annual admissions irrhosis of the liver to the General Hospital, Colombo, 156 (0·4% of the total admissions). Of 1789 necropsies rmed during this period 3·07% were on cases of cirrhosis e liver.

ylon appears to occupy an intermediate position, gards the prevalence of cirrhosis, between European tries and certain tropical countries. The death-rate cirrhosis per 100,000 of the population was 32·6 in ras (average for the ten years 1923-32) whereas in land and Wales it was only 4·7 (average for nine years -28). The necropsy figures for India have varied with different parts of the country—4·4% in Madras, 9·3% izagapatam, and 6·9% in Calcutta. On the whole have been high compared with the figures in Europe g., 1% in Berlin (Menon and Annamalai 1935).

he age-distribution and sex-distribution of 102 ents admitted for cirrhosis of the liver under the care e of us (P. B. F.) to the General Hospital, Colombo, 941–47 were as follows :

Age (yr.)	*No. of cases* *Male*	*Female*
1–9	1	0
10–19	1	1
20–29	5	5
30–39	10	8
40–49	34	2
50–59	15	2
60–69	9	5
70–79	4	0
80 or more	0	0

The ratio of males to females was about the same in the total admissions to these wards, indicating that there is no greater susceptibility to the disease in either sex. However, females seem to get cirrhosis at a younger age.

The racial distribution was as follows :

Race	*No. of cases*	*Percentage of total admissions*
Sinhalese	86 (83·5%)	84·9
Tamils (Ceylon) ..	8 (7·7%)	2·9
Indian Tamils.. ..	5 (4·8%)	4·7
Muslims	4 (3·9%)	3·7
Burghers	0 (—)	3·6
Others	0 (—)	0·2

The incidence of cirrhosis in the different races seems to correspond to the general racial distribution in the total admissions except in the case of Ceylon Tamils. In view of the fact that they are mainly vegetarians, their disproportionate representation in the cirrhosis group is noteworthy.

Except in 9 patients in whom the diagnosis was made at necropsy or by biopsy the clinical picture in the remaining 93 patients was typical of portal cirrhosis and was characterised by ascites in 96·7% and hæmatemesis in 17·6%. The clinical histories of the great majority, however, fell into two clear categories. In one group there was a definite history of an illness characterised by jaundice and biliuria preceding the onset of the cirrhosis ; in the other the onset was insidious, there being no history of jaundice but only of vague ill health, weakness, loss of appetite, &c., followed by the gradual development of ascites and the other signs of portal cirrhosis. The appearances of the liver at necropsy or on biopsy were also distinct in the two groups. In the former group the liver was coarsely nodular and showed microscopically collections of hyperplastic liver cells lacking the normal structure of the liver lobules and separated by areas of scar tissue (figs. 1 and 3). In the latter group the liver was more finely granular and fibrous, showing microscopically a more uniform fibrosis affecting the portal region and breaking up the liver lobules, of normal structure, into fragments or groups (figs. 2 and 4). Both clinically and pathologically these two categories correspond to toxic cirrhosis and multilobular cirrhosis or Laennec's cirrhosis (Boyd 1940). There were 15 cases in the former group and 87 in the latter.

TOXIC CIRRHOSIS

Ascites was the most important presenting condition and was found in all 15 cases ; it had developed insidiously and had persisted for months in most cases. In 12 cases there was œdema of the legs, which had developed later than the ascites. The liver was enlarged in 4 cases and the spleen in 3. A severe attack of jaundice had preceded the development of ascites in 12 of the 15 cases. In 2 of these there had been an attack of jaundice associated with ascites, and after an intervening period of good health the ascites alone had recurred. In 1 there had been only jaundice at the original attack ; a year later ascites had set in. In 9 cases the jaundice had persisted up to the time of admission into the hospital, the average duration being 90 days (range 30–240 days). In all these 9 patients the ascites had developed insidiously in the course of the jaundice. In 1 case no history was available, the patient being dull and drowsy on admission. In 2 cases there was no jaundice at any time, and there was nothing to distinguish them from Laennec's cirrhosis. However, a biopsy in the case of one and necropsy in the other showed that the condition was toxic cirrhosis. Lawrence (1946) reported a case of subacute necrosis of the liver without icterus and referred to 12 other cases. These 2 cases are interesting in providing further evidence that toxic cirrhosis may not infrequently occur without a previous history of jaundice. Apparently in such cases a series of attacks of " acute

Tuberculosis Association

At the annual meeting it was decided that this organisation's name should be changed to the British Tuberculosis Association.

Edinburgh Post-Graduate Board for Medicine

On Tuesday, Aug. 3, at 4.30 P.M., in the anatomy lecture theatre of Edinburgh University, Prof. D. F. Cappell will lecture on the Present Position of the Rhesus Factor.

Visitors' Entitlement to N.H.S. Benefits

The Ministry of Health announces (E.C.L. 60) that visitors to Great Britain, and visiting seamen, will be able to apply for treatment under the National Health Service.

Medical Historians Committee

A meeting of the United Kingdom, Dominions, and United States Official Medical Historians Liaison Committee will be held in Oxford from Aug. 3 to 7. The objects of this committee, which is sponsored by the governments concerned, is to provide opportunities for medical historians to consult together on technical questions. The committee's first meeting was held in Ottawa last September.

Advisers in Postgraduate Education

The governing body of the British Postgraduate Medical Federation on behalf of the University of London have made the following appointments of regional adviser in postgraduate medical education for the London metropolitan hospital regions: Mr. D. F. Ellison Nash (North-East); Dr. H. G. McGregor (South-East); Mr. P. H. Mitchiner (South-West). No appointment has yet been made for the North-West metropolitan region.

International Hospital Federation

Captain J. E. Stone, consultant on hospital administration and finance to King Edward's Hospital Fund for London, has been appointed hon. secretary and treasurer of this federation. The federation's secretariat will be established temporarily in the offices of the Fund, 10, Old Jewry, London, E.C.2.

The federation is an international organisation for the collection of national literature on hospital work and practice; the holding of international hospital congresses; the setting up of international study commissions; and the publication of reports, with a view to the improvement of hospital development, planning, equipment, technique, and administrative practice. The first international hospital congress will be held in Holland next June.

Compensation for Goodwill of Practices

Doctors who retired from practice or the personal representatives of doctors who died between the date of the passing of the National Health Service Act—Nov. 6, 1946 and July 5, 1948, and whose practices have not been sold in whole or part by July 5, 1948, should make early application to: the secretary of the Medical Practices Committee (Devonshire House, Mayfair Place, London, W.1), for a certificate that the conditions laid down in section 37 of the Act are satisfied. If the conditions are satisfied a claim for compensation for the loss of the right to sell the goodwill of the practice may be made on a form which the committee will supply. The completed claim form must be sent to the Ministry of Health by Oct. 31, 1948. Doctors on medical lists on July 5, 1948, will receive a claim form from the executive council for their area. Any doctor who does not shortly receive this form should apply to his executive council.

Superannuation of Mental Health Officers

The special rights of mental health officers under the National Health Service (Superannuation) Regulations, 1947, are supplemented under the National Health Service (Superannuation) (Amendment) Regulations, 1948. A leaflet (S.D.E.) explains that under the amending regulations a mental health officer who completes, or has completed, altogether 20 years' service in the new service and on equivalent duties before transfer will be able to qualify for retirement benefits at 55, and to count as double its length all service in the National Health Service scheme which is (*a*) after age 50 if the 20 years have been completed *by* that age, or (*b*) after the completion of the 20 years if this is *after* age 50. This provision will be of special advantage to officers transferred from mental-deficiency institutions or voluntary mental hospitals. Those who were under the Asylum Officers' Superannuation Act, 1909, or other statutory superannuation scheme have the option, on transfer to the N.H.S. scheme, to remain under the same conditions. This is explained in leaflet S.D.A.; and similar arrangements apply to nurses in voluntary hospitals (leaflet S.D.B.)

Ministry of Labour and National Service

Prof. I. G. Davies, Dr. T. G. Faulkner Hudson, J. A. L. Vaughan Jones have been appointed medical to the Ministry on the employment of the disabled.

Central Council for Health Education

The council are to issue to each of the local authorities in England, Wales, and Northern Ir exhibit dealing with a health topic; and from time this will be replaced by new material. This was by Mr. Henry Lesser, the retiring chairman, at the annual meeting in London on July 22. Mr. Le reported that the council are to provide free two-day in health education every two or three months at six universities. Mr. Lesser was succeeded as chairman E. K. Macdonald, medical officer of health for Leicester Dr. W. A. Bullough was elected vice-chairman.

World Health Organisation

Dr. G. Brock Chisholm, C.B.E., has been appointed director-general of W.H.O.

Dr. Chisholm, who is 52, served as a combatant in the war, winning the Military Cross and bar. He qualified in at Toronto in 1924 and was in general practice for several He then studied psychological medicine at the Maudsley and returned to Canada to work in Toronto as a psychiatrist the outbreak of the late war he resumed combatant command of the Lorne Scots, and successively of an infantry and of a military district. Later he became director of per selection and deputy adjutant-general of the Canadian Forces took a large share in devising and developing the personnel since adopted with modifications by the British and Ame armies. Having never previously been an army doctor, he appointed director-general of the medical services of the Canad army in the latter part of the war, with the rank of major-gen Thereafter he was deputy minister of national health and we for Canada before being appointed, two years ago, ex secretary of the W.H.O. interim commission.

CORRIGENDUM: *the late Captain Watson.*—The which reference was made in last week's memoir was *Teviotbank.*

* Amended notice

se 4.—A woman, aged 44, was in good health till she oped anorexia and vague ill health some months before sion. For four months her food had consisted mostly or 4 cups of rice conjee a day, and plain tea with sugar. or twice a week she would take rice with a little tomato and sambol, but often she vomited after this. She had ilk only about a dozen times during this whole period of nonths. At the end of this period she developed jaundice fter some weeks ascites.

se 5.—A woman, aged 27, developed anorexia in the month of pregnancy. For three months her food ted of a few pieces of bread with sambol and fish gravy on (she did not eat any fish), and a cup of malted milk e morning and night Three weeks after labour she oped jaundice.

se 6.—A man, aged 60, as a result of a domestic quarrel up taking any food at home for about three months. g this period his food, which he ate at tea kiosks, ted of plain tea with sugar and bread. He had no ıbles, milk, meat, or fish during the whole of this period. e end of it he developed ascites, for which he entered a hospital, and was cured after several weeks. He now ed his normal food and domestic relations and was in health for several months, when ascites recurred. In of treatment it persisted, and after six months he entered al on the present occasion. Biopsy of the liver at r's operation showed the toxic type of cirrhosis (fig. 5).

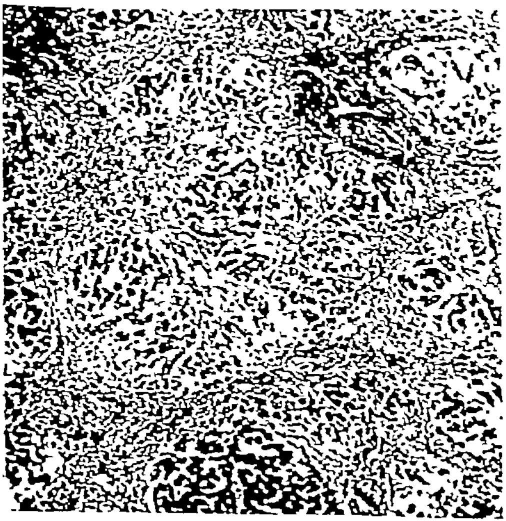
these 6 patients the diet was most deficient in its n content. Cases 4 and 6 are also of interest owing fact that condiments were absent altogether or nuch reduced for long periods preceding the onset illness. In the past when the emphasis was on positive cirrhotic agent in the diet, condiments often incriminated.

LAENNEC'S CIRRHOSIS

87 cases in this section fell into three groups ating the developmental stages of the cirrhotic s. Table I gives the main clinical findings in these groups.

I : Fatty Infiltration and Early Cirrhosis

e were 8 patients in this group : 3 females and 5 males. ver was greatly enlarged in all, the position of the border varying from three finger-breadths below stal margin to the level of the umbilicus. There was derness and no palpable nodularity on the surface. was no clinical condition such as amœbic hepatitis, stive cardiac failure, or tumour to explain the gement. In 4 cases, besides the enlargement, there scites, and the diagnosis of cirrhosis of the liver was not in doubt. In the remaining cases there was no ascites, but the enlargement was associated with the same evidence of liver dysfunction as in the cases with ascites. The Takata-Ara test was positive in all : the plasma-albumin level was reduced, in the 3 cases in which it was done, to an average of 2·25 g. per 100 ml. ; the hippuric-acid test showed an average of 30% of normal function in the 2 cases in which it was done ; and the van den Bergh reaction was indirect positive in 3.



-Section of liver shown in fig. 2: typical multilobular cirrhosis. (× 38.)

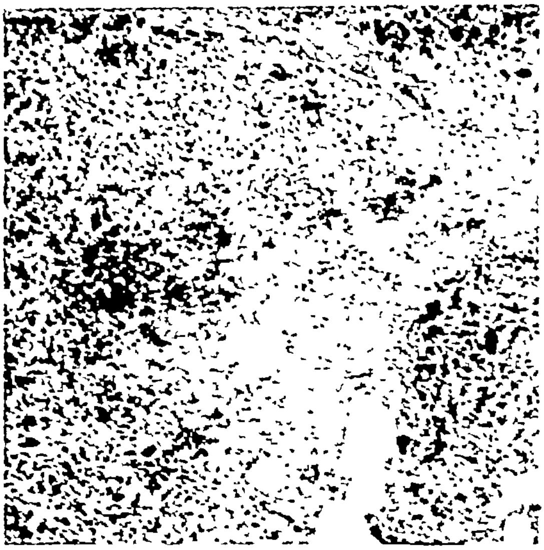


Fig. 5—Biopsy specimen of liver in case 6 : nodules of hyperplastic liver cells separated by wide areas of fibrous tissue containing numerous bile-ducts in some places. (× 85.)

The clinical diagnosis of fatty infiltration and early cirrhosis was confirmed by liver biopsy in the 3 cases in which it was done. Figs. 6, 7, 8, and 9 are photomicrographs of the histological sections from the liver in 2 of these cases.

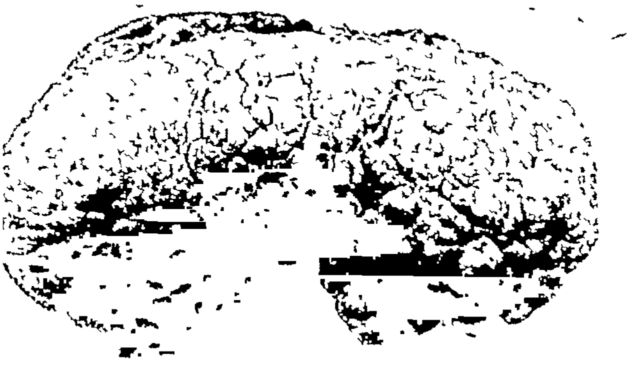
These patients were treated with a good diet consisting of meat, fish, milk, rice, bread, vegetables, fruits, &c. In addition glucose, mercurial diuretics, and dehydrocholin were given by injection to those with ascites. The average stay in hospital was about a month ; 4 patients left without much improvement ; 2 were discharged very much improved and free of ascites ; 1 patient developed pneumococcal meningitis and died (she developed clinical jaundice during the illness) ; 1 died after laparotomy. Of the 2 patients who were discharged relieved, 1 was readmitted after about six weeks for hæmatemesis of which he died. At necropsy Laennec's cirrhosis was found, with considerable fatty infiltration of the liver cells.

Group II : More Advanced Stage

There were 19 patients in this group : 5 females and 14 males. The liver was palpable on the average about two finger-breadths below the costal margin, and the edge was firm and elastic. Eighteen patients had ascites, and 3 hæmatemesis also. The spleen was enlarged in 7, and there was œdema of the legs in 7 ; the œdema had developed subsequent to the ascites. One patient had neither ascites nor hæmatemesis but was admitted in a cachectic state, with a hard and palpable liver ; he died eleven days later, and necropsy showed Laennec's cirrhosis.

The treatment in this group was the same as in the previous cases ; in addition paracentesis abdominis was done whenever abdominal distension indicated it ; 5 patients improved on treatment and were discharged free of ascites ; 10 patients left unrelieved ; and 3 died

already referred to.



. 1—Toxic cirrhosis of liver in a man aged 52 : liver coarsely nodular, with some nodules more than 2 cm. in diameter.

llow atrophy in miniature " occur without obvious undice but leading eventually to cirrhotic changes. In ch cases the clinical differentiation from Laennec's rhosis will be very difficult.

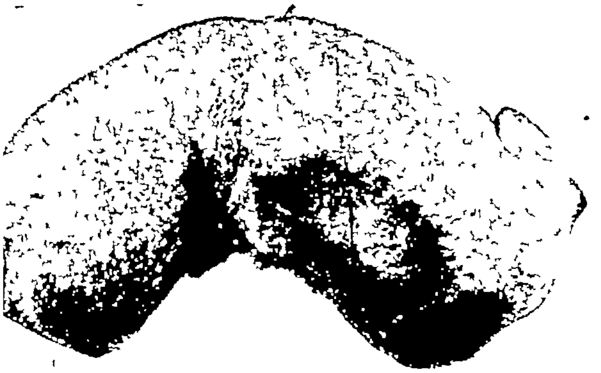
In the early stages of toxic cirrhosis the lowered ısma-albumin level seems to be an important factor the production of ascites, for in 2 cases the ascites sappeared with improvement in the plasma-albumin vel. In the later stages portal obstruction appears to the main factor concerned in the production of ascites.

6 cases repeated paracentesis and removal of large antities of fluid were necessary to relieve the abdominal stress, and in 2 of these reaccumulation of fluid was evented only by surgical measures. In 3 of these cases which the plasma-protein levels were determined the umin was well above the critical level at which lema develops. In 2 patients there was repeated ematemesis in spite of normal bleeding-time and otting-time, providing further evidence of the high gree of portal obstruction present in these cases.

boratory Findings

The laboratory findings were in keeping with the nical findings and indicated liver dysfunction. In 8 the 14 cases examined the van den Bergh gave a phasic reaction on admission; in 4 it was indirect sitive, and in 2 negative. In all 14 cases in which the kata-Ara test was done it was positive. In 7 cases which the hippuric-acid test was done it was below % of the normal function in 4 cases, and in the others tween 25 and 50%. The plasma-proteins were determned in 8 cases. The average total plasma-proteins per 0 ml. were 6·3 g., the albumin was reduced to an erage of 2·33 g., and the globulin was increased to 71 g. The average fibrinogen content was 0·27 g.

Of the 15 patients 4 were discharged apparently cured d free of ascites, in 2 the improvement following omentopexy; 3 patients left without improvement; and 8 died in hospital. In 3 cases the diagnosis was confirmed by necropsy and in 3 by biopsy of the liver. The livers were contracted and fibrotic, with a coarsely nodular surface, some nodules being more than 2 cm. in diameter, and the histological findings were those described for toxic cirrhosis (Boyd 1940).



. 2—Laennec's cirrhosis of liver in a man aged 40 : liver finely granular and fibrous.

Dietetic History

Of the 15 patients, 2 were of a higher economic level than the general non-paying class of patients studied. One, a vegetarian, took a daily diet which included bread, rice, vegetables, ghee, butter, and milk. The other had meat and fish as well. Of the remainder, 6 patients were of the average non-paying class, and their diet consisted of rice, bread, and preparations made of flour and vegetables; once or twice a week they had meat or fresh fish and on the other days dry fish. Condiments consisting of chillies, pepper, mustard, &c., were used in the preparation of the vegetables and fish curries. Fats were obtained in the form of coconut and coconut oil. The amounts of eggs and milk in these diets were negligible. One patient was too ill to give a detail history of his diet, but his relations said that for sever months he took only one meal a day, consisting of abo six string hoppers, a preparation made of baked flo and each weighing about an ounce, and sambol, whic consists of ground chillies, onions, maldive fish, and lim juice or vinegar, in small quantities. For the other mea he had tea with sugar but no milk.

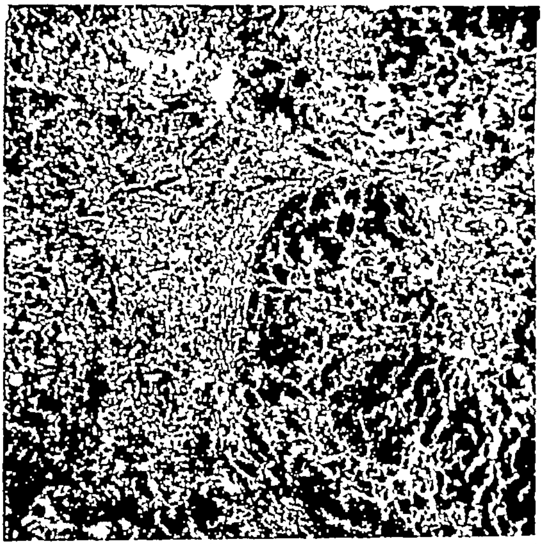


Fig. 3—Section of liver shown in fig. 1 : nodules of hyperplastic liv cells, with loss of normal lobular structure ; strands of fibrous tiss separating nodules contain numerous bile-ducts. (× 70.)

In 6 patients there was a definite history of dieteti deficiency preceding the illness :

Case 1.—A young man, owing to war-time food restri tions, used to eat only yams or preparations made of flou for about five days in the week. These were eaten plain o with a little coconut. On about two days in the week he too rice, and with this he had one or two vegetables. He too fish or meat only about twice a month but never milk or egg

Case 2.—A man, aged 45, had developed an illness charac terised by anorexia and recurrent attacks of fever, as a resul of which his diet had been very restricted, consisting on mos occasions only of rice conjee (water in which rice has bee boiled) After about seven months of this he develope jaundice and later ascites. He recovered with treatment but after some months of good health the ascites reappeared for which he now entered hospital.

Case 3.—A woman, aged 28, usually ate rice or bread and two vegetables. Meat or fish was taken only about once a month; milk never.

Case 4.—A woman, aged 44, was in good health till she eveloped anorexia and vague ill health some months before dmission. For four months her food had consisted mostly f 3 or 4 cups of rice conjee a day, and plain tea with sugar. Once or twice a week she would take rice with a little tomato urry and sambol, but often she vomited after this. She had ad milk only about a dozen times during this whole period of our months. At the end of this period she developed jaundice nd after some weeks ascites.

Case 5.—A woman, aged 27, developed anorexia in the ixth month of pregnancy. For three months her food onsisted of a few pieces of bread with sambol and fish gravy at noon (she did not eat any fish), and a cup of malted milk n the morning and night. Three weeks after labour she developed jaundice.

Case 6.—A man, aged 60, as a result of a domestic quarrel gave up taking any food at home for about three months. During this period his food, which he ate at tea kiosks, consisted of plain tea with sugar and bread. He had no vegetables, milk, meat, or fish during the whole of this period. At the end of it he developed ascites, for which he entered a local hospital, and was cured after several weeks. He now resumed his normal food and domestic relations and was in good health for several months, when ascites recurred. In spite of treatment it persisted, and after six months he entered hospital on the present occasion. Biopsy of the liver at Frazer's operation showed the toxic type of cirrhosis (fig. 5).

In these 6 patients the diet was most deficient in its protein content. Cases 4 and 6 are also of interest owing to the fact that condiments were absent altogether or very much reduced for long periods preceding the onset of the illness. In the past when the emphasis was on some positive cirrhotic agent in the diet, condiments were often incriminated.

LAENNEC'S CIRRHOSIS

The 87 cases in this section fell into three groups illustrating the developmental stages of the cirrhotic process. Table I gives the main clinical findings in these three groups.

Group I: Fatty Infiltration and Early Cirrhosis

There were 8 patients in this group: 3 females and 5 males. The liver was greatly enlarged in all, the position of the lower border varying from three finger-breadths below the costal margin to the level of the umbilicus. There was no tenderness and no palpable nodularity on the surface. There was no clinical condition such as amœbic hepatitis, congestive cardiac failure, or tumour to explain the enlargement. In 4 cases, besides the enlargement, there was ascites, and the diagnosis of cirrhosis of the liver was not in doubt. In the remaining cases there was no ascites, but the enlargement was associated with the same evidence of liver dysfunction as in the cases with ascites. The Takata-Ara test was positive in all; the plasma-albumin level was reduced, in the 3 cases in which it was done, to an average of 2·25 g. per 100 ml.; the hippuric-acid test showed an average of 30% of normal function in the 2 cases in which it was done; and the van den Bergh reaction was indirect positive in 3.

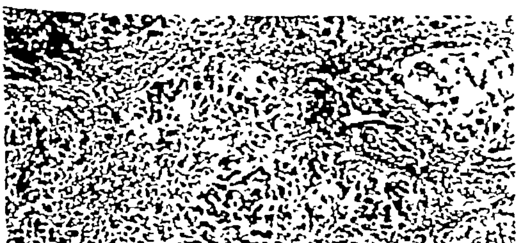

Fig. 4—Section of liver shown in fig. 2: typical multilobular cirrhosis. (× 38.)

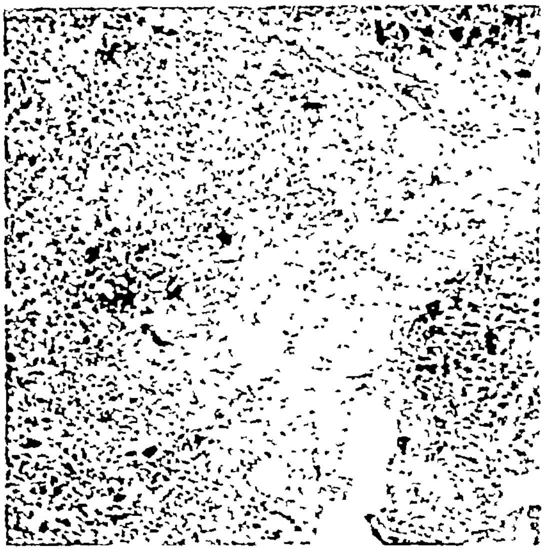

Fig. 5—Biopsy specimen of liver in case 6: nodules of hyperplastic liver cells separated by wide areas of fibrous tissue containing numerous bile-ducts in some places. (× 85.)

The clinical diagnosis of fatty infiltration and early cirrhosis was confirmed by liver biopsy in the 3 cases in which it was done. Figs. 6, 7, 8, and 9 are photomicrographs of the histological sections from the liver in 2 of these cases.

These patients were treated with a good diet consisting of meat, fish, milk, rice, bread, vegetables, fruits, &c. In addition glucose, mercurial diuretics, and dehydrocholin were given by injection to those with ascites. The average stay in hospital was about a month; 4 patients left without much improvement; 2 were discharged very much improved and free of ascites; 1 patient developed pneumococcal meningitis and died (she developed clinical jaundice during the illness); 1 died after laparotomy. Of the 2 patients who were discharged relieved, 1 was readmitted after about six weeks for hæmatemesis of which he died. At necropsy Laennec's cirrhosis was found, with considerable fatty infiltration of the liver cells.

Group II: More Advanced Stage

There were 19 patients in this group: 5 females and 14 males. The liver was palpable on the average about two finger-breadths below the costal margin, and the edge was firm and elastic. Eighteen patients had ascites, and 3 hæmatemesis also. The spleen was enlarged in 7, and there was œdema of the legs in 7; the œdema had developed subsequent to the ascites. One patient had neither ascites nor hæmatemesis but was admitted in a cachectic state, with a hard and palpable liver; he died eleven days later, and necropsy showed Laennec's cirrhosis.

The treatment in this group was the same as in the previous cases; in addition paracentesis abdominis was done whenever abdominal distension indicated it; 5 patients improved on treatment and were discharged free of ascites; 10 patients left unrelieved; and 3 died of liver failure besides the 1 already referred to.

Group III : Atrophic Stage

There were 60 patients in this group : 10 females and 50 males. The liver was contracted and impalpable. 53 patients had ascites, and 9 of these had hæmatemesis also. Three had hæmatemesis but no ascites. Four patients who had neither ascites nor hæmatemesis were admitted in a cholæmic state, and cirrhosis of the liver was diagnosed at necropsy.

The treatment was the same as in the previous groups. In 21 patients paracentesis abdominis had to be done, and in 3 surgical treatment was given to relieve the obstruction. Eight patients were discharged relieved of the ascites ; 33 left in much the same condition as they came in ; and 15 patients died besides the 4 already mentioned. The cause of death was cholæmia in 11, hæmatemesis in 4, heart-failure and anæmia in 1, and tuberculosis in 1. One patient collapsed and died after paracentesis abdominis, and 1 died of liver failure after operation. The diagnosis of cirrhosis was confirmed in all 8 cases in which necropsy was allowed.

Laboratory Tests

It was impossible to carry out all the laboratory tests mentioned in every case. Besides 6 patients who showed clinical jaundice as a terminal event, an indirect van den Bergh reaction was present in 35 of 70 patients examined (50%) ; in 31 cases (44%) it was negative. Bile-pigment was absent from the urine in 66 of 70 patients examined (94%). Clinical jaundice with excretion of bile-pigments, as against a slight icterus, was not foun in this group of cases.

TABLE I—CLINICAL FINDINGS IN LAENNEC'S CIRRHOSIS

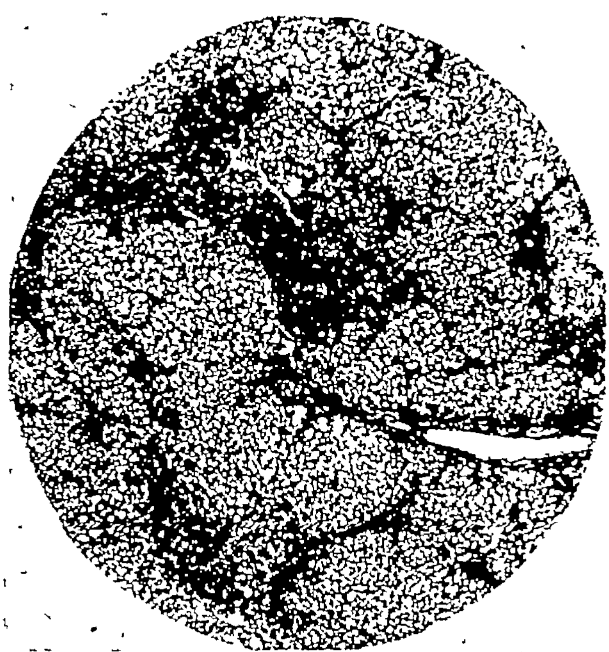

Fig. 6—Biopsy specimen of liver : extensive fatty infiltration and port fibrosis. Patient was a woman, aged 22, whose diet had been deficie in proteins and fats. No history of alcohol. (× 22.)

There was increased urobilinuria (more than 1/1 dilution) in 25 of the 64 patients examined. The Takata Ara test was positive in 63 of 68 patients examine (93%). Quick's hippuric-acid test showed that the live function was not more than 50% of normal in 85% o 41 patients examined. The plasma-proteins showed th changes characteristic of liver dysfunction. The serum albumin level was less than 4 g. per 100 ml. in 85% o 33 cases examined ; in 36% of cases it was even below 2 g. per 100 ml. On the other hand, the globulin was increased above 2 g. per 100 ml. in 79%.

Only 4 of the 53 patients examined had a hæmoglobin percentage above 75 (Dare's). The rest of the patients were anæmic, the average hæmoglobin percentage being 63. The anæmia was of the macrocytic hyperchromic type in 4 (7·5%) and macrocytic hypochromic type in 13 (24·5%). In 18 (34%) it was normocytic hypochromic. In 8 (15%) there was, in addition to a microcytic hypochromic anæmia, spherocytosis also. Thus the hæmatopoietic factor was deficient in nearly a third of the cases, and iron and the other materials necessary for hæmoglobin formation were lacking in about three-quarters. A normocytic normochromic anæmia was found in 6 cases (11%) and was apparently due to a hypoplastic condition of the marrow. The white cells were within the normal range in 28 of the 60 cases examined (47%); in 17 (28%) there was leucopenia ; and in 15 (25%) leucocytosis. The leucocytosis when present was polymorph in type. The platelets were reduced below 50,000 per c.mm. only in 1 case, but in 10 (20%) it was between 50,000 and 100,000 per c.mm. The clotting-time of blood was increased in only 1 of 48 cases examined

Ætiological Factors

Malaria and dysentery have been considered of importance in the ætiology of cirrhosis in the tropics. A history of malaria was available in 18 of the 87 patients (20·7%) in this group. Only 2 patients (1·3%) could remember having had dysentery. Of 31 patients whose stools were examined microscopically for dysentery only 1 was positive for *Entamœba histolytica*. As a control, 400 patients admitted to the medical wards of the hospital for various illnesses other than cirrhosis were questioned for a history of malaria and dysentery; 15·5% gave a history of malaria within a period of five years, and 6·5% of dysentery. The incidence of dysentery in the patients with cirrhosis is by no means greater than in the other patients, but the incidence of malaria was about 25% higher in the patients with cirrhosis.

Alcohol has long been recognised as of ætiological importance in cirrhosis. A history of alcohol was available in 19 (44%) of the 43 patients in whom a detailed dietetic history was available. Of these, 7 took alcohol only occasionally, and 12 (28%) took it daily. Of the 400 controls 28·5% were in the habit of taking alcohol, but 19% took it only occasionally; hence only 9·5% were regular alcoholics. The incidence of alcoholism among the cirrhotics is about three times that in the other patients.

Recent work has suggested that diet may be an important ætiological factor in the pathogenesis of cirrhosis. A detailed dietetic history was available in 43 cases. The diets fell into four main categories designated in the tables as A, B, C, and D.

Diet A is one in which, besides the staple food (rice or preparations made of flour), vegetables and some animal protein, such as dry fish, fresh fish, or meat, were consumed daily. Generally two good meals were taken at noon and night, and a light meal in the morning.

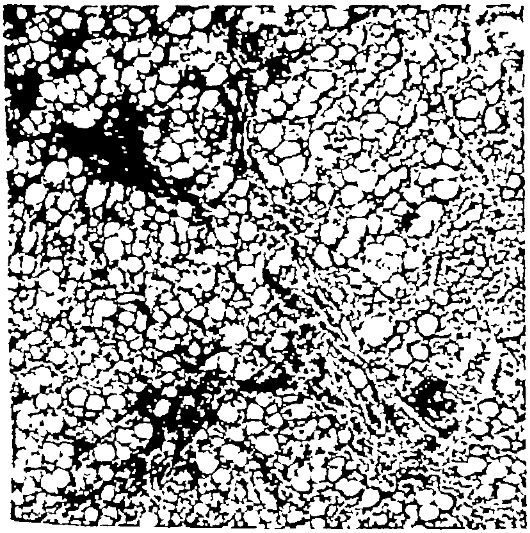

Fig. 7—Same as fig. 6. (× 90.)

Diet B consists of rice or preparations made of flour and vegetables taken daily with meat or fish about twice a week. The number of meals was three, as in A.

Diet C is similar to B except that no animal proteins are taken.

Diet D is a very deficient one; it normally consisted of rice or preparations of flour or some yams with about one vegetable; meat or fish was taken very infrequently, such as once or twice a month or not at all. Moreover, the quantities taken at a meal were insufficient, and the meals were not taken regularly, sometimes only one meal a day being taken.

The amount of eggs and milk consumed in any one of these diets is negligible. Condiments consisting of chillies, pepper, mustard, &c., are used as flavouring agents in the preparation of curries and are more likely to be present in greater quantity in the better-class diets which contain several curries than in the others. A sambol consisting of ground chillies, onions, maldive fish, and lime-juice or vinegar is usually taken in small quantities as an appetiser along with the rice and curries and may be considered as common to all categories of diets. Fats are usually obtained in the form of coconut and coconut oil.

It was impossible to determine from the history the actual quantities of the different foods consumed in these diets; however, Nicholls (1936) has measured the average daily amounts of proteins, fats, and carbohydrates per "man value" consumed by the poorer classes of the community in Ceylon, who live mainly on rice, dry fish, coconut, coconut oil, and vegetables. He found they consisted of 55·5 g. of protein, 32 g. of fat, and 365 g. of carbohydrates. This was the content of a diet that included fish daily. Diets B and C would correspond to this as regards carbohydrates and fats but inferior to it in proteins. Diet A would be better in the protein content but similar in fats and carbohydrates. Diet D would be inferior in all respects.

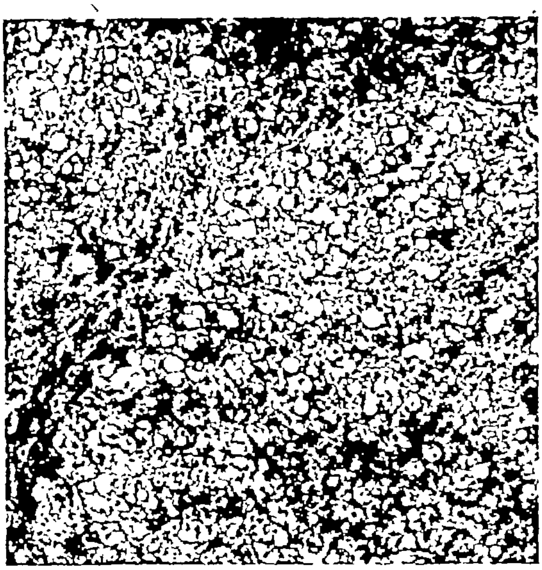

Fig. 9—Same as fig. 8. (× 70.)

Table II gives the distribution of the diets among the cirrhosis patients and among the 400 non-cirrhotic controls. It shows that the percentage of patients in the poorer categories of diets (C and D) among the cirrhosis patients is about four times that in the controls. Similarly, whereas 64·5% take a good diet (A) among the

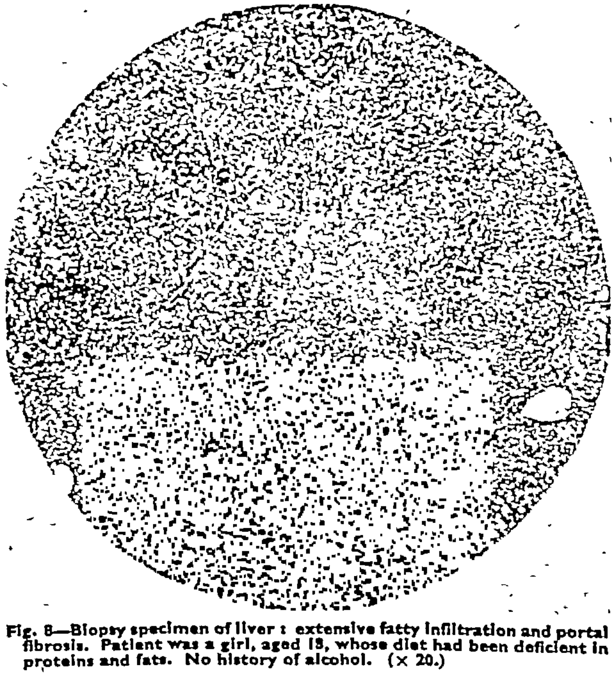

Fig. 8—Biopsy specimen of liver: extensive fatty infiltration and portal fibrosis. Patient was a girl, aged 15, whose diet had been deficient in proteins and fats. No history of alcohol. (× 20.)

controls, only about half that number do so among the cirrhotics.

The dietetic history of the patients in the group of "fatty infiltration" and early cirrhosis is particularly noteworthy, since in many of these cases the diagnosis has been confirmed by histological examination of the liver. In this group the dietetic history was available in 6. All belonged to category D.

One was also an alcoholic, who consumed about $1^{1}/_{2}$ bottles of arrack daily and, owing to loss of appetite, had neglected his meals for over one and a half years, though he was economically in a position to take a good diet.

Three were so poor that they could not afford to take regular meals, their food normally consisting of yams and coconut or rice and one vegetable; they were able to afford dry fish only very occasionally, once or twice a month. Nor were they able to afford even two good meals a day.

One patient was a postmaster in an inaccessible and isolated station for over two years. His regular meals consisted of rice with one vegetable or bread with plantains; meat, fish, eggs, or milk were not available for months. At the end of the period he developed ascites; in hospital he made good recovery on a good diet.

The remaining case was in a young woman who had developed anorexia. Vegetables, meat, fish, and milk made her sick, and for over a year her food consisted only of bread with sambol and plain tea with sugar. She was admitted to hospital because of progressive enlargement of the liver. None of these 5 patients took alcohol.

TABLE II—DIET AND CIRRHOSIS

Diet	Cirrhosis		Other diseases
	Including alcoholics	Excluding alcoholics	No. of cases
	No. of cases	No. of cases	
A	16 (37·2 %)	10 (32·2 %)	258 (64·5 %)
B	4 (9·3 %)	4 (12·9 %)	88 (22·0 %)
C	10 (23·2 %)	9 (29·0 %)	21 (5·25 %)
D	13 (30·2 %)	8 (25·8 %)	33 (8·25 %)
Total	43	31	400

DISCUSSION

The facts recorded here suggest that a history of an illness characterised by jaundice preceding the onset of cirrhosis is valuable evidence for differentiating toxic cirrhosis from Laennec's cirrhosis. The clinical picture in advanced stages of the two conditions may be identical, and some means of differentiating between them is desirable, since their pathogenesis, and therefore the prevention and treatment, are so different.

Toxic cirrhosis follows necrotising lesions of the liver, as the alternative names, postnecrotic cirrhosis and postnecrotic fibrosis, indicate. These necrotising lesions according to their severity are called acute or subacute yellow atrophy of the liver. Acute yellow atrophy has followed the administration of certain chemical compounds, such as 'Atophan,' for therapeutic purposes, and it has occurred in those exposed to certain industrial chemicals, such as trinitrotoluene and *tetrachlorethane*; idiopathic cases are met with most commonly in association with pregnancy, infective hepatitis, and homologous serum jaundice. The cause of the massive necrosis of the liver in these cases has been an enigma. Only a small proportion of those exposed to the chemical compounds or infections referred to develop it, and the pathological findings in the liver differ fundamentally from the diffuse zonal necrosis found in these infections (Mallory 1947). Himsworth and Glynn (1944), who noted the similarity of the massive necrosis of the liver in animals produced by a protein-deficient diet to that in human yellow atrophy, have suggested that the cause of massive necrosis is deficiency of the protective amino-acids in the blood reaching the liver. In infective hepatitis this deficiency may be due to faulty composition of the diet, or deficient intake of food, or the swelling of the liver inside the comparatively tough capsule may interfere with the blood-flow to certain regions. They have quoted impressive evidence in support of this view.

The question is whether massive necrosis may occur clinically apart from infective hepatitis, chemical poisons, &c., and owing to deficient diet alone. The occurrence of it in association with pregnancy uncomplicated by infective hepatitis favours such a possibility. In our 15 cases of toxic cirrhosis the clinical history in 8 suggested that the illness had started as an infective hepatitis, and that subacute yellow atrophy had set in as a complication. The diet in these cases was not deficient; and, if the pathogenesis of the liver necrosis is as described above, the protein deficiency must have been conditioned by the anorexia and vomiting and by swelling in the liver. In 6 patients definitely, and possibly in a seventh, a diet very deficient in proteins had been taken for a long time before the onset of the cirrhosis. In 4 of these a severe illness characterised by jaundice had set in after this period of dietetic deficiency, and this was later succeeded by the clinical picture of cirrhosis. In 2 a history of jaundice was absent altogether, though the pathological findings were those of toxic cirrhosis. In these 6 cases at least it looked as if the experiments of Himsworth and Glynn (1944) had been reproduced unwittingly.

The pathogenesis of the multilobular, or Laennec's, cirrhosis is different. Experimentally it has been produced by two different procedures. In one a hepatotoxic substance which produces a diffuse zonal type of necrosis of the liver has been administered at short intervals for a long time (Cameron and Karunaratne 1936); in the other either a high-fat diet or one deficient in lipotropic factors has been administered for a long time. This produces fatty infiltration of the liver, and prolonged fatty infiltration is followed by cirrhosis (Himsworth and Glynn 1944). The essential mechanism involved seems to be the constant absorption of the autolytic products of dead liver cells into the portal canals, where they stimulate the fibrous tissue to proliferate.

The conditions under which Laennec's cirrhosis develops in man are probably the same. An isolated injury, or one that operates at long intervals, is not likely to produce the repeated destruction of the liver parenchyma for long periods that is necessary. For this reason infective hepatitis, in which second attacks are uncommon and in which recovery usually occurs, with the development of considerable immunity (Havens 1947), is not likely to be a cause of Laennec's cirrhosis though it is the most important precursor of toxic cirrhosis. Malaria and dysentery, being self-limited diseases, are also unlikely to be of ætiological importance. Where people have been constantly exposed to toxic chemicals, as in certain occupations, cirrhosis has resulted (Butsch 1932, Poindexter and Greene 1934), though such cases are rare. Alcohol, which experimentally produces fatty infiltration of the liver (Rolleston and McNee 1929), has long been observed clinically to be an important ætiological agent of human cirrhosis. In Africa a high incidence of cirrhosis has been observed in those surviving the condition of malignant malnutrition, sometimes called kwashiorkor, in which severe fatty infiltration of the liver is a prominent feature (Gillman and Gillman 1945, Trowell and Muwazi 1945). The question is whether the cirrhosis which is so prevalent in the tropics, and in which neither alcohol nor severe malnutrition is a feature, may not be due to lipotropic deficiency in the diet.

A full dietetic history was available in only 43 patients of this group. There was no evidence that their diets contained more condiments than did those of the nonrhotic patients in the hospital. Nineteen patients con-sed to taking alcohol: of these 7 took alcohol only very casionally and 12 were regular alcoholics. In only ·9% therefore can alcohol be considered a cause of the rhosis. Eight patients had been subsisting for long riods on an all-round deficient diet, and 13 others had en on a diet whose protein and fat contents were below e requirements for health. The common factor in these patients (48·8%) was a diet deficient in proteins and ts, and the evolution of the pathological lesion in the er in these patients, as in the alcoholics, seemed to ve gone through an initial stage of fatty infiltration. the absence of a high-fat diet this fatty infiltration uld only have been due to lipotropic deficiency. The mmon dietary substances having high lipotropic tivity are, besides choline, animal proteins, such as r albumin, beef muscle, casein of milk, &c. Vegetable oteins are inferior in this respect (Hadfield and Garrod 47). Since the diets of these patients were very ficient in animal proteins, one may fairly conclude that 48·8% the cause of the cirrhosis was fatty infiltration the liver caused by lipotropic deficiency in the diet. the remaining 10 cases (23·3%) there was neither a story of alcoholism nor a deficient diet to explain the rhosis; nor had they ever had jaundice.

Whether the fatty infiltration of the liver observed in ronic alcoholism is due to a direct action of the alcohol the liver cells or to lipotropic deficiency induced by state of conditioned starvation has yet to be decided. he evidence in our series suggests that it may be due a direct action and not necessarily to concomitant tarvation. Of the 12 patients who were in the habit of aking alcohol daily and whose dietetic history was nown, 6 (50%) were in the dietetic category A and not nly took their meals regularly but also were in the habit f supplementing their regular meals with other food.

SUMMARY

The incidence of cirrhosis of the liver in Ceylon appears o be intermediate between its incidence in Europe and India.

A review is given of 102 cases of cirrhosis of the liver, ith special reference to the clinical types and their relaion to diet.

Of the 102 cases, 15 (14·7%) were toxic or postnecrotic irrhosis. In 8 of these 15 the cirrhosis had apparently ollowed infective hepatitis in persons on a good diet, hereas in 6 a long period of protein deficiency had receded the onset of the cirrhosis and appeared to have een concerned in the pathogenesis.

The remaining 87 cases (85·3%) were Laennec's irrhosis. Malaria, dysentery, and dietary condiments pparently played no part in the causation. In 48·8% f 43 patients in whom a detailed dietetic history was vailable the cause of the cirrhosis appeared to be fatty nfiltration of the liver due to lipotropic deficiency in the iet, whereas in 27·9% the cirrhosis was apparently due alcoholism. In 23·3% the cause of the cirrhosis was ot determined.

A history of an illness characterised by jaundice receding the onset of cirrhosis is considered valuable vidence for differentiating toxic cirrhosis from Laennec's irrhosis, in which the onset is insidious. The clinical icture in the late stages of the two conditions may be lentical.

We wish to thank Prof. W. A. E. Karunaratne and Dr. . H. Cooray, of the department of pathology, for their aluable help in studying the pathological material; Dr. . S. W. de Saram, Dr. G. R. Handy, and Dr. W. D. atnavale, pathologists of the General Hospital, for their oöperation; Prof. Milroy Paul, Dr. J. H. F. Jayasuriya, and r. A. S. Rajasingham, surgeons to the General Hospital, for btaining biopsy specimens of the liver, and Mr. G. Webster r the photomicrographs.

ACUTE ATROPINE POISONING

REVIEW OF EIGHT CASES

RICHARD B. WELBOURN
M.B. Camb., F.R.C.S.
SURGICAL REGISTRAR, LIVERPOOL ROYAL INFIRMARY; LATE CAPTAIN R.A.M.C., GRADED SURGEON

JOHN D. BUXTON
M.R.C.S., D.A.
ANÆSTHETIST COUNTY HOSPITAL, ORPINGTON, AND GUY'S UNIT; LATE MAJOR R.A.M.C., SPECIALIST ANÆSTHETIST

ACUTE atropine poisoning is not uncommon; it is fully discussed in the standard textbooks, and cases due to the ingestion of mixtures (Morton 1939, Comroe 1933, Alexander et al. 1946), the application of an ointment (Jones 1945), the accidental drinking of a liniment (Carter 1940), and the instillation of eye-drops (Duggan 1937, Hopkins and Robyns-Jones 1937) containing this alkaloid have been reported. No toxic reactions after the administration of atropine by subcutaneous injection have been reported in recent years.

Owing to an error in dispensing a stock solution, nine patients (cases 5–13 in the accompanying table) each received by subcutaneous injection atropine sulphate gr. $^1/_6$ instead of the gr. $^1/_{100}$ prescribed preoperatively. Four of these patients developed toxic signs and were observed by us. We have second-hand knowledge of four others (cases 1–4) who developed toxic signs. They probably received a similar amount of atropine, but the exact dose is not known. The main facts about the patients and the dates are shown in the table. All were young men with septic conditions requiring minor operations. Only one had a severe infection. The most severe cases were seen on Jan. 15, 1947, and it was not until after this that we suspected atropine poisoning. The whole incident was then investigated.

Case 8 received his atropine injection at 4 P.M. and was operated on at 5.15 P.M. At 6 P.M. he was excited, acutely confused, and hallucinated. His gait was ataxic. He was very talkative, though his speech was slurred, and he was disoriented both in time and in space. He asked to go to the toilet for a wash and brush-up, tried to put out an imaginary fire, addressed a girl friend by her nickname, looked inside people's coats, and so on. He seemed fatigued and allowed himself to be laid down, only to jump up again a few moments later. He even tried to kiss a male orderly. Though not aggressive he was very active and had to be forcibly restrained. He was flushed, and his pupils were dilated, but this was assumed to be due to his excitement. Nothing abnormal was noted about his pulse. He was thought to be in an acute confusional state precipitated by the anæsthetic and operation. Morphine gr. $^1/_4$ was given intravenously without effect. About half an hour later paraldehyde 6 ml. was given intramuscularly, and the patient was transferred to the psychiatric block, where he settled into a deep sleep. He awoke next morning to find himself considerably bruised. Remembering nothing of the previous night's

CASES OF ATROPINE POISONING

12	33	Average	Dark	Large perineal abscess, very toxic	1/4	,,	Nil	Nil
13	22	Large	,,	Abscess of arm	1/4	,,	,,	,,

happenings, he was alarmed to find himself under restraint. The psychiatrist could find no evidence of mental illness, and the patient was transferred back to the septic surgical ward. At 10 A.M. he was extremely apologetic, and appeared normal apart from his septic finger. His pupils were not dilated, and his skin and pulse-rate were normal.

Three other patients who had been operated on at the same time as case 8 were found the same evening to be behaving strangely four or five hours after receiving atropine:

Case 9 was sitting up in bed plucking at his bandage and talking in a confused manner. He was picking imaginary objects off his chest and placing them carefully on the locker beside his bed. He settled down and slept after being given an injection of 'Omnopon' gr. $^1/_3$ and scopolamine gr. $^1/_{150}$.

Case 10 was sitting up in bed, sewing his sheet with an imaginary needle and thread. He talked about his sewing and, when it was suggested that he should go to sleep, remarked that he could never sleep in the daytime (although it was now dark).

Case 11 insisted on getting out of bed repeatedly and attempted to light numerous imaginary cigarettes.

All the patients were mentally normal next morning, and showed no dilation of the pupils. The least severely affected (case 11) was the only one who remembered anything of the night's excitement. He also had blurring of vision, which passed off during the morning.

Some days previously two other patients had shown similar behaviour, though neither was observed by us:

Case 3 had stripped his bed and gone round the ward searching for a tall pair of steps so that he could climb on to a high shelf.

Case 4 had asked for a nail-brush and gone to the bathroom, where he stayed for a long time scrubbing his nails.

A few days earlier two patients (cases 1 and 2) had complained of blurring of vision on the morning after operation, and both stated that they had been troubled by nightmares. The blurring had passed off after a few hours and had not come to our notice at the time.

Behaviour under Anæsthesia

In cases 1–4 and 9–13 anæsthesia was induced by a small intravenous injection of soluble thiopentone (average 0·35 g.) and maintained by the inhalation of nitrous oxide and oxygen from a standard Boyle's apparatus. Case 8 did not have soluble thiopentone. In cases 5–7, under the care of another anæsthetist, a small amount of 'Trilene' (trichlorethylene) had been added to the gas-and-oxygen mixture.

Great difficulty was experienced in anæsthetisin case 8, and some difficulty was also noted with cases 9–11 Their pupils were more dilated than is usual afte atropine gr. $^1/_{100}$, but no importance was attached t this at the time. No excessive drying of mucosæ o tachycardia was observed. Difficulty was experienced in "settling" the patients with gas and oxygen; they either reacted violently to the stimulus of the operation on a normal gas-and-oxygen mixture or passed into the stage of jactitation when the oxygen percentage was reduced to deepen the level of anæsthesia. The reaction to the surgical stimulus persisted even in the presence of extreme cyanosis. Case 8, who received no soluble thiopentone, was the most difficult to balance. With cases 5–7, who also received trilene, the other anæsthetist found no great difficulty.

The rate of recovery was normal in all cases—i.e., the patients were conscious before leaving the theatre, and sufficiently rational to recognise their own boots and jackets. While waiting to be taken back to the wards some of them fell asleep, and none showed any abnormality in behaviour.

DISCUSSION

The symptoms and signs of atropine poisoning may be divided into two classes: (1) those due to paralysis of postganglionic cholinergic nerves, in particular dilated pupils, with blurring of vision, hot dry skin, suppression of secretions and alterations in heart-rate; and (2) those due to central nervous derangement, which include restlessness, confusion, delirium, hallucinations, and muscular incoordination. It is easy for the attention to be diverted from the peripheral autonomic signs by the more striking central nervous signs. This was so with cases 8–11, who were first seen in delirium in a dimly lit ward. After recovery there is no recollection of what has occurred.

Atropine is absorbed rapidly into the body. About two-thirds is destroyed in the liver, and a third is excreted in the urine within fourteen hours. In case 8 delirium came on within two hours of the injection of a toxic dose, and in cases 9–11 it was noted within five hours. Extreme dilatation of the pupils and difficulty in anæsthetising was found in little over an hour after the injection. In cases 3, 4, 8, 9, and 10 all toxic symptoms and signs passed off within eighteen hours, and in cases 1, 2, and 11 symptoms persisted for only another two or ree hours. Surprisingly these three had the mildest mptoms in our series. It is not unusual for recovery be delayed for several days.

It is interesting that omnopon and scopolamine ietened case 9. Had the nature of the condition been cognised when this was ordered, scopolamine would t have been used because of its atropine-like action; it this appears to have been outweighed by its depressive tion on the central nervous system.

The difficulty in anæsthetising could be explained first ; the increased stimulation of the central nervous stem, especially the higher centres, and secondly by e basal metabolic rate, which is said to be raised ter atropinisation.

Doses up to gr. $^{1}/_{30}$ of atropine usually produce the fects of parasympathetic paralysis; gr. $^{1}/_{12}$ produces ese effects and restlessness; and doses of gr. $^{1}/_{8}$ or ore produce mental symptoms and ataxia. Nine atients (cases 5–13) received doses gr. $^{1}/_{6}$, which is n times the maximal pharmacopœial dose, yet only ur of them (cases 8–11) showed toxic effects. All were ealthy young men, who gave no history of having aken medicines containing atropine or similar drugs. t is therefore unlikely that any had an acquired tolerance. ndividual variations in susceptibility to atropine are ommon; but apart from this there are several possible easons for the tolerance of the remaining five.

Cases 5–7 were anæsthetised with trilene, which has more powerful and lasting depressive action on the entral nervous system than has gas-and-oxygen or oluble thiopentone in the small doses given to these atients. Perhaps this prevented the onset of restlessness nd delirium. Conversely, case 8, who was the most elirious of all, did not even have the benefit of depression due to soluble thiopentone. Case 7, who was not affected, had trilene, but not soluble thiopentone.

Case 12 had a very large collection of pus (about 2 pints) nd was very toxic. He was pale and weak and in great pain; his pulse was rapid and thin. Such patients, being already depressed by the action of bacterial toxins, sually require small amounts of anæsthetic, and it may ell be that they require correspondingly large doses of timulants to produce delirium. Case 13 is more difficult o explain. He also had a large collection of pus, but as not nearly so ill as case 12. He was a large man f dark complexion; his size may be significant but his omplexion is probably not. Cases 8–11 were all fair-omplexioned, but 3 of the earlier group of toxic patients ases 2–4) were dark. It has already been remarked that ases 8–11 were suboxygenated during anæsthesia, and his may have helped to precipitate the delirium. Case 8 he worst) had been the most deeply cyanosed, and in ll cases the delirium was not apparent until after næsthesia.

SUMMARY

Eight cases of acute poisoning from atropine used in remedication for anæsthesia are described.

Six of these patients developed acute delirium, but all ecovered completely.

Four of them and five others who showed no toxic igns are known to have received atropine sulphate r. $^{1}/_{6}$ as a result of an error in dispensing.

The symptoms and the difficulty in anæsthetising the atients are discussed.

Reasons are suggested for the tolerance of five patients o such a large dose.

Trilene anæsthesia appears to have antagonised the entral nervous actions of the atropine in three of these ases.

We wish to thank the Director-General of Army Medical ervices for permission to publish this paper. The cases ere treated in a military hospital overseas. The dispensing rror was made by a foreign civilian pharmacist, employed n the hospital dispensary, who was familiar with the metric system and confused by the Imperial system of dosage. We wish to thank our colleagues for permission to quote their cases and for help in the investigation.

MEMBERS OF THE MEDICAL RESEARCH COUNCIL INDUSTRIAL MEDICINE RESEARCH UNIT, BIRMINGHAM ACCIDENT HOSPITAL

A FORM of dressing which will keep out both liquids and bacteria from an open wound has long been needed. The dressings now available commercially are mostly made of synthetic rubber-like materials such as polyvinyl chloride, which have the serious disadvantage of rendering the underlying skin sodden. The horny layer becomes macerated, the edges of wounds tend to gape, and there are many theoretical objections, such as the danger of washing bacteria from adjacent parts of the skin into the wound. The wetness of the skin comes not only from sweat-gland secretions but also from insensible perspiration.

Up to now it has been tacitly accepted that material which is waterproof must have this disadvantage, but in the search for suitable clothing for tropical warfare a new principle was established. A material can be proof against liquid water (and so keep off tropical rain) and yet be pervious to water vapour (thus allowing the sweat and insensible perspiration to evaporate underneath the clothing and pass through in vapour form). Applied to occlusive dressings this principle implies that a dressing can keep out liquids and yet allow evaporation from the underlying skin. Accordingly an approach was made to the technical plastic experts.

The range of plastics now available includes substances with a very high resistance to water in liquid and vapour form—e.g., polyvinyl chloride and 'Polythene.' It also includes other substances which are highly permeable to water vapour, such as 'Cellophane' (uncoated) and other cellulose derivatives, polyvinyl alcohol, and various 'Nylon' derivatives. The substances in each class vary enormously in their chemical and mechanical properties. Films of the cellophane-like substances, for example, though tested clinically by Bloom (1945) and others, are naturally brittle when dry, and are only kept pliable by the *incorporation* of plasticisers—e.g., glycerin and tricresyl phosphate. Even when plasticised they are relatively inelastic and can be torn easily at the edges of the film. Polyvinyl alcohol, unless specially treated, is soluble in water. Some of the newer nylon derivatives have excellent mechanical properties. They are tough, pliable in themselves without the addition of any plasticiser, and somewhat elastic.

EXPERIMENTAL NYLON-DERIVATIVE FILM

One of the nylon derivatives, offered to us in the form of experimental film, showed such promising qualities that it was decided to experiment with this substance. The absence of a plasticiser is particularly desirable, since the film is unlikely to change its properties, and there are no risks of toxic effects when it is applied to the surface of an open wound.

The film has been supplied to us in sheets having an even thickness of about $^{3}/_{1000}$ in. It is fully transparent, and even in this thickness quite tough. It can be sterilised by dry heat at 150°C without deterioration, though it cannot be boiled in water without softening and adhering to itself. Though soluble in 80% alcohol it is insoluble in most of the common industrial solvents—e.g., trilene, oils, cold water, weak acids, and alkalis. Its permeability to water vapour in a thickness of $^{1}/_{1000}$ in. is about 8000 g. per 100 sq. m. per hour at 40°C, with a differential water-vapour pressure across the film equivalent to 53 mm. Hg. This permeability is of the same order as that of cellophane, and may be compared with the hourly water-vapour loss from the total human body surface (about 1·8 sq. m.) of about 20–25 g. of insensible perspiration. The corresponding figures for plastics of low water-vapour permeability, such as polythene, are about 60 g. per 100 sq. m. per hour under the above conditions.

Tests on the Film as a Barrier to Micro-organisms

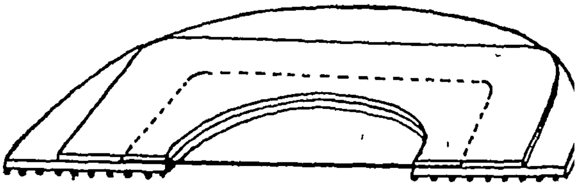
By means of experiments with a dressing applied to a model limb Dr. L. Colebrook (personal communication) has shown that micro-organisms readily pass through dressings as soon as they become moist with water or with serum. The dressings tested included cotton-wool pads carefully applied under crêpe bandages. The organisms which pass most readily through these dressings are motile, such as *Ps. pyocyanea*. Non-motile organisms—e.g., hæmolytic streptococci—can also pass through, though more slowly. For comparative purposes it was decided to test the ability of the plastic film to restrain the passage of *Ps. pyocyanea.* The most exacting conditions were ensured by containing a small quantity of broth-culture of the organism inside a sac made of the plastic and immersing it in sterile broth. At 24 hours the surrounding broth was still sterile, though the pigment from the bacterial culture had diffused through the plastic membrane. Similarly, a moist dressing incorporating the nylon-derivative film on a mock limb effectively stopped the passage of the organisms. Other experiments showed that, though electrolytes passed through the film, particles as large as hæmoglobin were restrained. These tests showed conclusively that the film was free from pin-holes and was an efficient barrier against bacteria.

Tests on Human Skin

Though theoretically the water-vapour permeability of the plastic was great enough to allow the passage of all the insensible perspiration from the skin, it is impossible to mimic the conditions of a dressing perfectly by in-vitro tests. Accordingly two pieces of film, each about 4 in. square, were applied to the forearm, and the edges sealed down with adhesive plaster. One piece of film was polythene, with a low water-vapour permeability, and the other was the selected nylon derivative. Within two hours the difference between the two films was apparent. The impermeable film had beneath it a thin layer of liquid water, which ran from one part of the "dressing" to another when it was squeezed against the skin of different areas. In contrast, the skin under the nylon-derivative film appeared normal. After removal of the films the skin under the polythene was obviously sodden, and several minutes elapsed before the water had evaporated sufficiently to allow a finger run over the area to detect the normal smooth and somewhat slippery surface of dry skin, whereas the skin beneath the nylon-derivative film looked and felt dry. This finding was confirmed under dressings worn much longer (up to ten days). These experiments confirm that the skin under the experimental nylon-derivative film is unlikely to become excessively moist.

Difficulties of Sealing a Plastic Film Dressing

The difficulties of sealing a film to the skin round the edges so as to ensure completely waterproof protection under conditions comparable with those that the workman would encounter with his hands are very great. Initi experiments were made with a finger-stall of the plast film, but it was very difficult with available adhesives a "sticking plaster" to ensure a complete seal round t base of the finger. With the coöperation of Mess Smith & Nephew a partial answer to the problem has be obtained by using "window frames" made of polyvin material coated with adhesive. The nylon-derivati film is incorporated at its edges between two layers of t adhesive polyvinyl material, leaving one adhesive surfa for application to the underlying skin (see figure). The windows adhere satisfactorily to the skin for day provided that the skin is free from grease when they a first applied and is not too heavily coated with hair. Wh oil is rubbed over the dressing, the adhesive is loosened a the dressing tends to ride up. For the special circu stances of workers in oils, therefore, some addition forms of attachment may be required—e.g., painti over the edges of the adhesive with acrylic resin. any case, if the part covered is to be subjected to appre able mechanical strain or friction, the dressing is be held in place with a light cover of plain or crêpe bandag In industry this bandage could be changed daily, leavi the underlying plastic seal untouched, thus permitti safe inspection of the wound and cosmetic cleanline of the outer cover. In short, though other practic difficulties may no doubt arise, the possibility of a effective bacteria-proof dressing which will leave t underlying skin in a normal state has been demonstrate



Diagrammatic section of occlusive dressing, showing upper adhes frame, transparent nylon-derivative film, and lower adhesive fra with protective crinoline (dotted line).

Effect on Skin Bacteriology

Before conducting therapeutic trials of the value such a dressing applied to wounds, it was though desirable to determine the effect of such a dressing o the bacteriology of normal skin. This trial has consider able theoretical interest in addition to its possible futur practical applications. It is known that the norma skin has appreciable self-sterilising properties against many organisms. These properties probably reside mainly in its fatty-acid content, though they may also be assisted by the action of lysosyme and other substances (Burtenshaw 1945). The bacteriology of ordinary skin exposed to the air, contact with the nose, &c., is complicated by many bacteria which can be regarded as simple surface contaminants. What will be the effect of covering the skin in such a way as to remove the possibility of surface contamination for days? The experiment is of special importance with regard to *Staph. aureus*. Studies by Williams and Miles (1945) have shown that this is the commonest contaminating organism of small wounds, and is probably the major cause of sepsis in small wounds in industry. Many studies, including a recent report from this unit (Moss et al. 1948), have indicated that the main source of these organisms, both in wounds and on normal skin, is the nose.

If normal skin is covered with the plastic dressing for different periods of days, a characteristic change in the bacterial flora is observed. In an investigation of the skin of hospital patients, control areas before application of the dressing and adjoining areas at the time of its removal yielded *Staph. aureus* in 39 out of 77 cases (50·6%). The methods of swab culture were designed

demonstrate *Staph. aureus* in small numbers and there-
e included an anaerobic broth technique as well as
robic culture on blood-agar plates (Williams and Miles
45). In a series of 24 observations *Staph. aureus* has
ver been recovered from under plastic dressings which
ve remained firmly sealed for three days or more,
ough in 14 of these it was recovered from the adjoining
in. This observed difference is statistically highly
nificant ($\chi^2 = 10{\cdot}8$, $P = 0{\cdot}001$).

Examination of the direct blood-agar plate not only
pplied data on the presence or absence of *Staph. aureus*
t also revealed another difference between normal and
cluded skin. The occluded skin yielded only a few
pes of bacterial colonies in contrast to the adjoining
in, from which a great variety of colonies were isolated.
rther investigation of the organisms which survive on
e occluded skin shows them to be gram-positive
agulase-negative cocci, most of which give biochemical
actions similar to those of *Staph. epidermidis*. That
ese effects on the bacterial flora are not due to any
tiseptic action of the nylon derivative is demonstrated
in-vitro control tests. *It is thus clear that normal*
in, cut off from outside contamination, can free itself
om such pathogenic organisms as *Staph. aureus*.

In-vitro tests showed that penicillin was not inacti-
ted by the film. Tragacanth is a convenient vehicle
r the application of penicillin under the dressings, since
does not loosen the adhesive. Under completely
aled dressings penicillin in tragacanth (0·2 ml. of
),000 units per ml.) dried to form a continuous pellicle,
d in several cases the occluded skin was found to be
erile.

rial as Wound Dressing

A clinical trial of the dressings for industrial and other
ounds is now in progress. Preliminary results show
at such a dressing is practicable and that wounds
der it remain dry and heal well. The transparency of
e film makes it possible to inspect the progress of healing
ithout disturbing the aseptic barrier. Exposure to
l may interfere with adhesion; this can be partly
bviated by wearing a bandage over the dressing, and
is bandage can be changed as required. When a
omplete seal is maintained, added infection cannot
ake place, though sepsis cannot always be prevented
the wound is infected before the dressing is applied.

DISCUSSION

These experiments with a plastic film which combines
atisfactory mechanical properties with a high perme-
bility to water vapour demonstrate its suitability as
dressing material. Under this material skin remains
ry and free from contamination and its considerable
antibacterial powers are given full scope. The design
of the dressings can doubtless be modified to facilitate
application to particular areas and to improve adhesion,
but it is felt that the principle of a dressing sealed but
permeable to water vapour has now been established.

The nylon-derivative material used was an experi-
mental batch, and further supplies are not yet obtainable.

SUMMARY

The physical properties (in particular water-vapour
permeability) of a nylon-derivative film suitable for
wound dressings are described.

The film is an effective barrier against micro-organisms.

Tested on human skin, the permeability of this film
to water vapour is sufficient to prevent the skin becoming
odden.

The bacterial flora of the healthy skin under the
cclusive dressing becomes modified: *Staph. aureus*
isappears, and the variety of organisms is reduced.

Clinical trials with the film as a wound dressing are
n progress, and preliminary results are promising.

We are indebted to Dr. Leonard Colebrook, director of the Medical Research Council Burns Unit, for his advice; to Mr. A. M. Hood for some of the bacteriological work; and to Mr. J. C. Swallow, PH.D., and his colleagues of the Plastics Division of Imperial Chemical Industries Ltd., to Messrs. Courtaulds Ltd., and to Messrs. T. J. Smith & Nephew Ltd., for their assistance in the development of the occlusive dressing.

VITAMIN E (TOCOPHEROLS) IN THE COLLAGENOSES

J. F. BURGESS
M.D. Montreal, F.R.C.P.(C.)

From the Department of Dermatology, Montreal General Hospital

The increasing recognition of the importance of vitamin E (mixed tocopherols) in health and in disease and the knowledge gained from clinical and histopathological studies in certain dermatoses warrant a brief summary of its therapeutic uses.

Vitamin E consists of several fat-soluble tocopherols, of which α, β, γ, and δ tocopherols have been isolated in their natural state: α-tocopherol is found in cotton-seed oil and is also produced synthetically; β-tocopherol is obtained from wheat germ; and γ-tocopherol and δ-tocopherol are derived from soya bean. The natural tocopherols are extracted by vacuum distillation from these various sources.* Vitamin E is therefore called here vitamin-E complex.

ATOPIC DERMATITIS

As a result of personal observations, a series of cases of atopic dermatitis were treated over a period of nearly a year with vitamin-E complex by mouth. In several cases sebaceous secretion increased, with the appearance of comedones and dilated follicles where these had not been present before, together with exacerbation of a pityriasis capitis often accompanied by greasy scales indicating seborrhœic dermatitis. In the absence of any signs pointing to endocrine overactivity, it was thought that vitamin-E complex might possibly affect sebaceous-gland activity and therefore fat-metabolism. Harris et al. (1947) have reported the stimulating effect of vitamin-E complex on quantity and quality (increased cream) in the production of cow's milk.

GRANULOMATOUS ULCER OF LEG

A long-standing case of granulomatous ulcer of the leg, compatible with a diagnosis of necrobiosis diabeticorum lipoidica and characterised histopathologically by the presence of necrobiotic collagenous zones with lipoidal deposition, was treated with 2000 mg. of mixed tocopherols given intramuscularly in ten days (Burgess and Pritchard 1948a). (In the light of more experience intramuscular injections of 100–300 mg. of mixed tocopherols twice weekly are better tolerated.) Favourable response was evident clinically within a week, and the patient, a female aged 53, was treated with mixed tocopherols by mouth for four months. Histopathological studies a month after the institution of therapy and again four months later, long after clinical cure, revealed the important finding that, coincident with the disappearance of lipoidal depositions, a considerable regeneration of degenerated collagen bundles had resulted, and indeed a demonstrable re-formation and rehabilitation of elastic-tissue fibres. Three months after the treatment had been stopped ulcers recurred

The film has been supplied to us in sheets having an even thickness of about $^{3}/_{1000}$ in. It is fully transparent, and even in this thickness quite tough. It can be sterilised by dry heat at 150°C without deterioration, though it cannot be boiled in water without softening and adhering to itself. Though soluble in 80% alcohol it is insoluble in most of the common industrial solvents—e.g., trilene, oils, cold water, weak acids, and alkalis. Its permeability to water vapour in a thickness of $^{1}/_{1000}$ in. is about 8000 g. per 100 sq. m. per hour at 40°C, with a differential water-vapour pressure across the film equivalent to 53 mm. Hg. This permeability is of the same order as that of cellophane, and may be compared with the hourly water-vapour loss from the total human body surface (about 1·8 sq. m.) of about 20–25 g. of insensible perspiration. The corresponding figures for plastics of low water-vapour permeability, such as polythene, are about 60 g. per 100 sq. m. per hour under the above conditions.

Tests on the Film as a Barrier to Micro-organisms

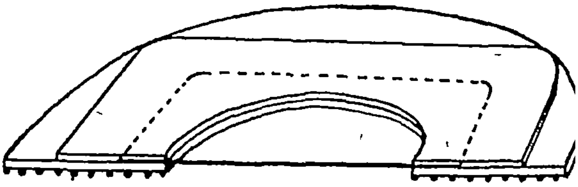
By means of experiments with a dressing applied to a model limb Dr. L. Colebrook (personal communication) has shown that micro-organisms readily pass through dressings as soon as they become moist with water or with serum. The dressings tested included cotton-wool pads carefully applied under crêpe bandages. The organisms which pass most readily through these dressings are motile, such as *Ps. pyocyanea*. Non-motile organisms —e.g., hæmolytic streptococci—can also pass through, though more slowly. For comparative purposes it was decided to test the ability of the plastic film to restrain the passage of *Ps. pyocyanea*. The most exacting conditions were ensured by containing a small quantity of broth-culture of the organism inside a sac made of the plastic and immersing it in sterile broth. At 24 hours the surrounding broth was still sterile, though the pigment from the bacterial culture had diffused through the plastic membrane. Similarly, a moist dressing incorporating the nylon-derivative film on a mock limb effectively stopped the passage of the organisms. Other experiments showed that, though electrolytes passed through the film, particles as large as hæmoglobin were restrained. These tests showed conclusively that the film was free from pin-holes and was an efficient barrier against bacteria.

Tests on Human Skin

Though theoretically the water-vapour permeability of the plastic was great enough to allow the passage of all the insensible perspiration from the skin, it is impossible to mimic the conditions of a dressing perfectly by in-vitro tests. Accordingly two pieces of film, each about 4 in. square, were applied to the forearm, and the edges sealed down with adhesive plaster. One piece of film was polythene, with a low water-vapour permeability, and the other was the selected nylon derivative. Within two hours the difference between the two films was apparent. The impermeable film had beneath it a thin layer of liquid water, which ran from one part of the "dressing" to another when it was squeezed against the skin of different areas. In contrast, the skin under the nylon-derivative film appeared normal. After removal of the films the skin under the polythene was obviously sodden, and several minutes elapsed before the water had evaporated sufficiently to allow a finger run over the area to detect the normal smooth and somewhat slippery surface of dry skin, whereas the skin beneath the nylon-derivative film looked and felt dry. This finding was confirmed under dressings worn much longer (up to ten days). These experiments confirm that the skin under the experimental nylon-derivative film is unlikely to become excessively moist.

Difficulties of Sealing a Plastic Film Dressing

The difficulties of sealing a film to the skin round the edges so as to ensure completely waterproof protection under conditions comparable with those that the workman would encounter with his hands are very great. Initi experiments were made with a finger-stall of the plas film, but it was very difficult with available adhesives ar "sticking plaster" to ensure a complete seal round t base of the finger. With the coöperation of Mess Smith & Nephew a partial answer to the problem has be obtained by using "window frames" made of polyvin material coated with adhesive. The nylon-derivati film is incorporated at its edges between two layers of t adhesive polyvinyl material, leaving one adhesive surfa for application to the underlying skin (see figure). The windows adhere satisfactorily to the skin for day provided that the skin is free from grease when they a first applied and is not too heavily coated with hair. Whe oil is rubbed over the dressing, the adhesive is loosened ar the dressing tends to ride up. For the special circun stances of workers in oils, therefore, some addition forms of attachment may be required—e.g., paintir over the edges of the adhesive with acrylic resin. I any case, if the part covered is to be subjected to appre able mechanical strain or friction, the dressing is be held in place with a light cover of plain or crêpe bandag In industry this bandage could be changed daily, leavin the underlying plastic seal untouched, thus permittin safe inspection of the wound and cosmetic cleanline of the outer cover. In short, though other practic difficulties may no doubt arise, the possibility of a effective bacteria-proof dressing which will leave th underlying skin in a normal state has been demonstrate



Diagrammatic section of occlusive dressing, showing upper adhes frame, transparent nylon-derivative film, and lower adhesive fra with protective crinoline (dotted line).

Effect on Skin Bacteriology

Before conducting therapeutic trials of the value o such a dressing applied to wounds, it was though desirable to determine the effect of such a dressing o the bacteriology of normal skin. This trial has consider able theoretical interest in addition to its possible futur practical applications. It is known that the norma skin has appreciable self-sterilising properties against many organisms. These properties probably reside mainly in its fatty-acid content, though they may also be assisted by the action of lysosyme and other substances (Burtenshaw 1945). The bacteriology of ordinary skin exposed to the air, contact with the nose, &c., is complicated by many bacteria which can be regarded as simple surface contaminants. What will be the effect of covering the skin in such a way as to remove the possibility of surface contamination for days? The experiment is of special importance with regard to *Staph. aureus*. Studies by Williams and Miles (1945) have shown that this is the commonest contaminating organism of small wounds, and is probably the major cause of sepsis in small wounds in industry. Many studies, including a recent report from this unit (Moss et al. 1948), have indicated that the main source of the organisms, both in wounds and on normal skin, is the nose.

If normal skin is covered with the plastic dressing for different periods of days, a characteristic change in the bacterial flora is observed. In an investigation of the skin of hospital patients, control areas before application of the dressing and adjoining areas at the time of its removal yielded *Staph. aureus* in 39 out of 77 cases (50·6%). The methods of swab culture were designed

which, however, yielded satisfactorily to further treatment with vitamin-E complex.

LUPUS ERYTHEMATOSUS

It was logical, in view of the grouping by Klemperer et al. (1941) of certain diseases with a common collagenous degeneration, that such diseases should be similarly investigated therapeutically. Our attention was consequently directed to lupus erythematosus, and the results of therapy in 25 cases have been studied clinically and histopathologically (Burgess and Pritchard 1948b). The value of treatment with mixed tocopherols in this disease was very favourable, with some reservations. All the cases treated were of the more or less widespread but fixed types. Superficial cases of lupus erythematosus, no matter how old, responded almost specifically to tocopherol therapy in doses of 100–300 mg. by mouth. Long-standing cases with much infiltration, follicular plugging, and evident sclerosis and fibrosis yielded partially to treatment much more slowly on vitamin-E complex 300–600 mg. daily, best administered on an empty stomach. One case of long standing, with a good deal of thickening in plaques on the face, yielded only slightly in that the thickening disappeared early. In some of these cases obvious but irremovable foci of infection would have a detrimental effect on the therapeutic value of curative agents. The severe cases were those encountered in the clinic, whereas superficial lesions yielding very satisfactorily to vitamin-E complex were seen in private practice. This probably has to do with relative adequacy of diet.

Histopathological studies in lupus erythematosus revealed that, apart from the inflammatory cellular reaction, evidence of collagenous degeneration was difficult to demonstrate in superficial lesions, whereas in old-standing infiltrative lesions sclerosis of the collagenous bundles was evident. Inflammatory infiltrates generally disappeared relatively rapidly and, in chronic cases with marked thickening, partial regeneration of collagenous tissue was demonstrable. A considerable hypertrophy of the epithelial layer of the skin and follicles is constantly found in lupus erythematosus; therefore it is an important fact that this hypertrophy disappeared relatively early in the course of treatment. In some apparently cured cases lupus erythematosus recurred. It is obvious that either total histopathological regeneration had not resulted and the treatment had been stopped too soon, or these patients required the administration of mixed tocopherols daily to maintain a satisfactory tissue-tocopherol level consistent with their normal needs. One case of twenty-five years' duration recurred, after cure, while still under treatment with tocopherol. After the extraction of three infected teeth the response to continued tocopherol therapy was rapid, illustrating the point that the factor of infection should not be overlooked and that the tocopherols should be looked on as aids in treatment in conjunction with other sound well-proved measures.

Those patients who were photosensitive did exceedingly well under this form of therapy. Photosensitivity was lost, and the patients could go about in the sun in normal fashion and get tanned.

SCLEROSIS OF THE LEGS

Our attention was next directed to sclerosis of the legs, associated with ulcers (Burgess and Pritchard 1948c). Shute et al. (1948) have also reported the results of treatment of leg ulcers with vitamin E. The clinical picture in these cases is consistently the same. Leg ulcers, with or without eczematisation, develop commonly in the lower third of one or both legs and are not infrequently viewed as "stasis" or "varicose" ulcers, particularly if œdema is present. The clinical picture is made up of a more or less sclerotic condition of the legs, in some patients only moderately apparent through "feel," in others the skin being hidebound, resulting in limitation of ankle movements (with or without varicosities, which are often present to a minor degree), together with single or multiple ulcers, often callous, and of long duration or of frequent recurrence.

In the present series we tried to assess tocopherol therapy without other additive measures such as compresses, antiseptic ointments, and complete rest in bed. The results were particularly good in that the sclerosis disappeared with the healing of the ulcers. The older the patient, the greater the fixity of the sclerotic process and hence slower response to therapy. Cure of the infective ulcerative process is undoubtedly hastened if tocopherol therapy is combined with other measures, notably antibiotic remedies either applied locally or given parenterally.

OTHER COLLAGENOSES

Experience with dermatomyositis, lichen sclerosis et atrophicus, scleroderma, morphea, and granuloma annulare has shown varied response to tocopherol therapy but in the main favourable. These observations parallel the experiences of Brigadier R. M. B. MacKenna (personal communication).

DISCUSSION

In our studies, clinical observation of the results of treatment with mixed tocopherols in the enumerated diseases with a common degenerative collagenous state has been closely correlated with histopathological studies. Further, vitamin-E complex has been given both intramuscularly and by mouth, without the administration of vitamins A, B, or C, which might lead to uncertainty in assessing the results.

Action of Vitamin-E Complex.—The possible synergistic or sparing action of vitamin E on vitamin A, B, or C could only have an effect on what might be absorbed in the daily food intake. This synergistic action may be the rôle of vitamin-E complex but it does not seem logical or probable. On the other hand, it seems much more likely that vitamin-E complex exerts a profound influence on enzymatic reactions within the cells—e.g., that of hyaluronidase. In the vegetable world where the tocopherols are created (the synthesis of vitamin E by animals or by bacteria has not been reported) the association is again with the cytoplasm rather than with th oil depots (Hickman and Harris 1946). The tocopherols a known to exert an antioxidant action, as Hickman an Harris point out, and they are profoundly necessary in th maintenance of the structure of the cells whereby th cells through enzymatic action further coördinate othe metabolic activities.

Infection.—Lupus erythematosus, necrobiosis wit ulcer formation, dermatomyositis, granuloma annular and sclerosis of the legs with ulcer formation are al associated with infection either in situ or in some othe part of the body. It is possible that scleroderma ma be precipitated by obscure infections. Common bana infections (streptococcal, staphylococcal, &c.) are easil demonstrated in leg ulcers, discharges, &c. Perhap virus infections may be not unimportant in the collagenoses. The sclerosis in cases of leg ulcer is alway much more pronounced in the ulcerated leg. It may be that infection causes the sclerosis or that the sclerosis once present, is exaggerated by the presence of infection. That trauma is a factor in these leg-ulcer cases is shown by the fact that numerous incisions made for biopsy of sclerotic tissue before treatment have become the site of ulcers indistinguishable from those for which the patient sought treatment. We have had similar experience in a biopsy wound of the wrist through a plaque of morphea showing neither infection nor circulatory change.

After-treatment.—In all these cases of degenerative collagenoses where apparent cure has been obtained with vitamin-E complex further treatment is needed to retain the patient's health. The normal intake of vitamin E in food is about 15–30 mg. daily. Therefore patients with these degenerative states cannot acquire, assimilate, or utilise to advantage vitamin-E complex in the daily food intake. It may therefore be necessary to give large amounts of the concentrated product. Perhaps in large doses vitamin-E complex exerts an antioxidant action, whereas in normal amounts it does not. More knowledge will be gained about requirements for prevention in individual cases. However, it is suggested that for a long time various amounts of crude wheat germ which has not been defatted should be added daily to the diet.

The skin is perhaps one of the largest and one of the most underestimated organs of the body. It is the most accessible and the most easily observed, and the pathological changes are but a mirror of those which may affect many organs. Further, the highest normal concentrations of vitamin E appear in the spleen, lungs, and muscle of the heart (Hickman and Harris 1946). Numerous reports have already appeared about its value in various diseases. The applicability of vitamin-E complex in many other degenerative diseases may therefore be justified.

I am grateful to Abbott Laboratories for liberal amounts of vitamin E, and to British Drug Houses for further supplies.

OCCUPATIONAL ANEURYSM OF THE PALMAR ARCH

REPORT OF A CASE

D. W. Short
M.B., B.Sc. Glasg., F.R.C.S.E.
ASSISTANT IN THE ORTHOPÆDIC DEPARTMENT, GLASGOW ROYAL INFIRMARY

Aneurysms of the palmar arteries are usually traumatic. Most are false aneurysms which have developed after a penetrating wound of the palm, the term "false" being reserved for cases where no part of the aneurysm sac is derived from the parent wall. True aneurysms are rare. Middleton (1933) collected 16 reported cases of true palmar aneurysm. Of these, 14 were associated with trauma, and 2 were regarded as having developed spontaneously. Middleton subdivided the traumatic true aneurysms into two classes: (1) acute, where the aneurysm followed a single definite contusion; and (2) chronic or occupational, where the condition followed repeated minor injuries. Of Middleton's collected cases, 6 were examples of occupational true aneurysm, and he contributed 2 more of his own. I have found accounts of 2 other cases, and report here 1 of my own.

Michans et al. (1936) reported one in an old woman of 68 and attributed it to the use of a rolling-pin. A tumour had been present in the hypothenar eminence for $2^{1}/_{2}$ years, and it had gradually swollen until, at the time of examination, it was about 2 in. in diameter. It was soft and reducible and had a palpable but not visible pulsation, and on auscultation over the swelling a systolic murmur of medium intensity was heard.

Gee (1945) described another case in a soldier, who had a tender swelling in the left hypothenar eminence, which had appeared 3 months previously when he had had to man the pumps intermittently for nearly 4 days. The lump had gradually enlarged and become more tender. It was a tense cystic swelling, 1 in. long by $^{3}/_{4}$ in. wide. Expansile pulsation could be felt, but there was no audible bruit.

In neither of these cases was there any neurological or vascular disturbance of the hand.

CASE-RECORD

A marine engineer, aged 28, came to the orthopædic department complaining of a tender lump in his right palm of 6–7 weeks' duration.

He had served in the Merchant Navy for about 5 years. About 9 months previously he had been transferred to a ship with a stiff reversing lever, which he shifted by hammering with the "heel" of his right hand. After doing this for about 2 months, he had begun to have a continual bruised feeling at the base of the thumb, and he had noted increasing tenderness over this area, and a swelling which appeared to become larger.

On examination there was an almond-shaped tumour about an inch long at the base of the hypothenar eminence and just distal to the pisiform bone. It seemed to be deep to the palmar fascia and was not attached to the overlying structures. It was not mobile or pulsatile and felt like a cyst. There was no impairment of movement of wrist or fingers or any other abnormality. The Wassermann reaction was negative.

Operation.—The swelling was explored after a tourniquet had been applied. It was found to be a saccular aneurysm arising from the superficial palmar arch immediately distal to the deep branch of the ulnar artery. It was not adherent to the surrounding tissues, and the adjacent ulnar nerve appeared healthy. The artery was ligated proximal and distal to the aneurysm, and the sac was excised. The saccular dilatation arose from the superficial aspect of the artery. It was about three-quarters of an inch long, with a thin smooth bluish wall, and was filled with firmly adherent thrombus.

Pathological report (Dr. R. I. Shaw Dunn).—"An aneurysmal sac measuring 8 × 6 × 5 mm. is present and it contains laminated thrombus. The wall of the sac is thin and partly atrophic, with small deposits of altered blood in its substance. Reactive changes are seen, with organisation of the periphery of the thrombus."

Progress was uneventful, and the patient returned to work a month later.

DISCUSSION

Traumatic true aneurysms in the palm are very uncommon. Though they have occasionally arisen from various parts of the superficial and, more rarely, the deep palmar arches, most of them are associated with the ulnar artery and are found deep to the inner border of the hypothenar eminence.

The clinical diagnosis may be difficult, especially when, because of their site and because the aneurysmal sac is filled with organising thrombus, no pulsation is detectable. Bradley (1945) described an acute true aneurysm in which no pulsation was felt, and in his view this is often so. Wapshaw (1936) suggested that a preliminary aspiration might be useful in diagnosis. Gee (1945), in his case, made two unsuccessful attempts to aspirate blood, and subsequently at operation found that the needles had entered the sac of the aneurysm but it was completely occluded by organising clot.

The first symptoms have often been a persistent bruised feeling, with a tender swelling appearing later. Sensory disturbances are sometimes prominent; but, in view of the close proximity of the ulnar nerve, it is interesting that such symptoms are so frequently absent. Neurological signs are more commonly present in false aneurysms, but here, in some cases at least, the neurological upset is probably due to the original injury rather than to the aneurysm.

SUMMARY

A case of true occupational aneurysm of the superficial palmar arch is reported.

The term "occupational" is reserved for those aneurysms attributed to repeated minor injuries—in

this case the practice of hammering a stiff lever with the palm of the hand.

The first symptom was a persistent bruised feeling, which was first noted about two months after the patient had started this practice, and the swelling was noted four months later.

The operative findings and subsequent progress are described.

This is a rare condition, and only 10 other published cases were found.

I wish to thank Mr. J. Patrick, surgeon-in-charge, orthopædic department, Glasgow Royal Infirmary, for permission to publish this case; Dr. R. I. Shaw Dunn for his report on the pathological specimen; and Prof. J. W. S. Blacklock, of the department of pathology, Glasgow Royal Infirmary, for permission to publish this report.

ASSOCIATED ECTOPIC ANUS AND UTERUS DIDELPHYS

REPORT OF A CASE

A. J. UNDERWOOD-WHITNEY
M.B. Camb.
HOUSE-SURGEON, WESTMINSTER HOSPITAL

A GIRL first attended Westminster Hospital in 1934 at the age of 18 months. At birth her anus had been found to be in the fourchette. This opening had proved inadequate, and an inguinal colostomy had been performed at the age of 4 months.

The ectopic anus barely admitted a lead pencil; it was not dilatable, and there was no sign of a sphincter. The skin of the natal cleft at the normal site for an anus contracted on stimulation, suggesting that the sphincter was present in the normal position. The anus and anal canal were therefore dissected free and transferred to the normal position, to open through a well-defined mass of muscle-fibres lying just under the skin. No abnormality of the vagina was noted at this time. The new anus was kept dilated at regular intervals for some months, and after two years the colostomy was closed, the child then being 3½ years old. The new anus worked very well, and after a year or two the patient was lost sight of.

The patient reappeared at the age of 13 years in September, 1945, at the outpatient department at Westminster Hospital. The presenting symptom was an offensive vaginal discharge noted fourteen days after her first menstrual period two months previously and continuous since then.

The previous operation appeared satisfactory; the anus was lax, but there was an active anal reflex. The mother said that control was normal. There was a profuse offensive vaginal discharge, the exact origin of which could not be seen.

In December, 1945, the patient was admitted to hospital for investigation. Examination under anæsthesia revealed that the discharge was coming through a small sinus high up in the right lateral fornix, and that pressure on the right lateral wall of the vagina, which was bulging medially, produced a profuse brownish discharge, suggesting that the sinus led into a cavity lying beside the vagina. The cervix and uterus appeared to be small, but otherwise normal. After a radio-opaque fluid had been injected through the sinus, radiography showed a cavity lying to the right of the vagina and extending from level of the vaginal vault to that of the vulva. This was thought to be probably a dermoid cyst associated with the congenital malformation of the proctodæum.

An attempt was made to remove this cyst by dissection through the perineum. Owing to great difficulty in dissecting the cyst from the vaginal wall, however, the incision, which was made along the line of junction of the right labium minor with the right vaginal wall, was carried through into the cyst, and the extent of the cyst was explored. The cyst contained a large quantity of foul-smelling grumous fluid with numerous small crystals of cholesterin. After this had all escaped, a speculum was passed into the cavity, and a small cervix was seen protruding into the vault. In fact there was a uterus didelphys, with a septate vagina, the right labium minus meeting the septum and not the right lateral wall of the vagina. Hence a unilateral hæmatocolpos had resulted which was slowly discharging through the small sinus connecting the two halves of the vagina at their upper ends. As much as possible of the septum in the vagina was removed, and the right labium minor was joined to the right lateral wall of the vagina.

Postoperatively the patient made an uninterrupted recovery. When seen as an outpatient two months later she had still a slight discharge vaginally, but it was no longer offensive.

I wish to thank Mr. G. T. Mullally for his helpful criticism and permission to publish this report.

PYLORIC OBSTRUCTION WITH TETANY AND COMA

REPORT OF A CASE

H. GORDON UNGLEY
V.R.D., M.D. Durh., F.R.C.S.
HONORARY SURGEON, ROYAL WATERLOO HOSPITAL, LONDON;
LATE SPECIALIST IN SURGERY, ROYAL NAVY

THE case reported here presented problems of diagnosis largely as a result of the absence of a history at the time of admission.

A naval shipwright, aged 42, was admitted at 2.30 P.M. on May 24, 1942, with 3 days' history of constipation. He denied any other symptoms and would not give further information in response to leading questions.

It was only revealed during his convalescence that he had deliberately concealed a long history of indigestion and had instructed his wife to do the same, through fear of losing his job.

On admission: temperature 96·4°F, pulse-rate 61 per min. Grossly emaciated, with sunken cheeks and hollow eyes betokening severe dehydration. Rectum empty; a simple enema gave no result. Abdomen retracted, but no mass or abnormality detected.

May 25: general condition had deteriorated. At 9 A.M. another enema was given, with poor fæcal result. At 11 A.M. patient vomited a few ounces of black fluid. Hiccuping started. Patient was now only semiconscious, and twitchings in the limbs were noted. At 1 P.M. he was unconscious and a convulsion started. No focal point evident. A tonic spasm, with inhibition of respiration, was followed by a period of relaxation and stertorous breathing. On examination after seizure, no abnormality in reflexes, tone, or muscular power was demonstrable. Fundi normal; pupils reacted to light and accommodation. Blood-pressure 108/67 mm. Hg, pulse-rate 60 per min. Urine contained albumin but no other abnormality.

Blood-count: red cells 5,160,000 per c.mm., Hb (Sahli) 110%, colour-index 1·06; white cells 14,200 per c.mm. (polymorphs 75%, lymphocytes 11%, large mononuclears 13%, eosinophils 1%). Blood-urea 124 mg. per 100 ml.

Cerebrospinal fluid: 3 ml. of clear fluid; cells 2 per c.mm., most being lymphocytes; protein 70 mg. per 100 ml.; globulin normal.

Differential diagnosis made by physician in charge: (1) secondary deposits in brain from carcinoma of stomach; and (2) uræmic convulsions associated with alkalosis of unknown cause.

May 26: patient still unconscious, with periods of semi-consciousness. His condition being grave, surgical opinion was sought. Now showed advanced emaciation and dehydration; abdomen board-like all over; respiration entirely thoracic; liver dullness appreciably diminished; soft fæces in rectum; bladder slightly distended; no abnormality found in rectum or pelvis. It was decided that immediate laparotomy offered the only hope of saving the patient's life; and generalised peritonitis was tentatively diagnosed. The fits, hæmoconcentration, and high blood-urea level remained unexplained.

Urine just before operation: sp. gr. 1014; reaction neutral; a cloud of albumin; no sugar; many polymorphs and some epithelial cells and red cells; no casts.

Intravenous drip infusion of saline and glucose was set up as soon as the decision to operate had been made.

Operation (May 26).—A midline upper abdominal laparotomy was performed under local infiltration anæsthesia with 1 in 1000 'Nupercaine' assisted by gas-and-oxygen inhalation and a trace of ether. There was no free fluid or peritonitis; stomach enormously hypertrophied and moderately distended; duodenum beyond pyloroduodenal junction collapsed and shrunken to a diameter of $^3/_4$ in. Clearly an advanced stenosis from duodenal ulceration was present. Radial streaks of white were seen in mesentery of upper jejunum, looking like fine pieces of string lying in subperitoneal tissue. Stomach was emptied of thick foul black fluid with stomach-tube passed by anæsthetist. Gastrojejunostomy was rapidly performed. During operation patient stopped breathing several times and required artificial respiration. After operation patient was kept on operating-table $1^1/_2$ hours before it was considered advisable to move him to his bed.

In the theatre and later in the ward the following ancillary treatment was given: (1) intravenous infusion of isotonic glucose and saline, which had been set up before operation, was continued postoperatively for 24 hours; (2) inhalation of oxygen and carbon dioxide was continued for 6 hours after the anæsthesia had ceased; (3) stomach-tube was left in for 24 hours; and (4) foot of bed was raised so that bed was at an angle of 15° from horizontal.

Postoperative progress.—Patient regained consciousness at 10 A.M.—i.e., 22 hours after the operation. Memory had been much affected by the illness: he said he had a hazy recollection of some events on May 22, but that nothing remained in his mind from that date until the morning after the operation. He was told by his wife that he had made morning tea on May 23, but he had no recollection of this. This five-day amnesia remained permanently.

Intravenous fluids, including hypertonic saline to raise the blood-chlorides, were stopped at 2.30 P.M. on May 27 after 5 pints had been given. Watery drinks by mouth were tolerated well.

May 28: milky drinks were started on this day and were much appreciated by the patient; and 10 ml. of 10% calcium gluconate was given intravenously. He slept almost the whole day except for his feeds, which did not disturb him, because he went instantly to sleep after each one.

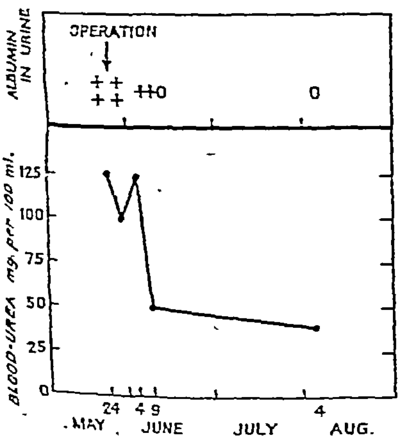

Fig. 1—Chart showing albumin in the urine and fall in blood-urea level after operation.

Subsequent progress.—Apart from a few bouts of hiccup in the next few days, the patient continued to make excellent progress. On June 1 he was still very languid but was taking food and drinks well. Convalescence proceeded uneventfully, and he was allowed up in a chair on June 17—i.e., 22 days after operation. On July 4 he was sent on sick leave for 28 days.

On his return to hospital on Aug. 1 he was almost unrecognisable—he looked so fat and well. He had gained $1^1/_2$ stone and could now take a good mixed diet without discomfort, provided that the meals were small.

The patient was last seen in November, 1947, when he said he had remained in good health and was enjoying a mixed diet. He could eat fish and various meats and vegetables, but pain and flatulence were caused by the following articles of diet: tinned food (such as sardines, herrings, and baked beans); fish and meat pastes; sausages, pork, and any meat made up with seasoning, as in vienna steaks; curries and meat soups; cauliflower, brussels sprouts, and onions; and certain fried foods.

Figs. 1 and 2 show the changes in the blood-urea, albuminuria, and urine chlorides during the postoperative period.

The findings at operation made it clear that the emaciation, dehydration and thirst were explained by pyloric stenosis. The generalised abdominal rigidity, fits, cramps, and loss of consciousness were associated with the alkalosis and the consequent tetany.

ADDITIONAL INFORMATION

The following details of the preoperative state and the history of prolonged gastric symptoms were only obtained from the patient and his wife in the period of convalescence. This information had been withheld on admission for the reasons already stated above.

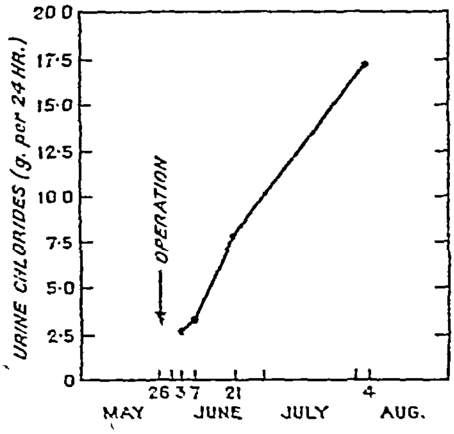

Fig. 2—Chart showing rise in excretion of chlorides in urine.

In 1937 the first symptoms of "indigestion" were experienced—an epigastric pain relieved by MacLean's powder in a few days. Patient remained well until May, 1940, when he went to bed for five days because of stomach pain and thereafter returned to duty and was on a diet for four weeks with complete relief.

In August, 1940, symptoms recurred, and patient was under treatment intermittently from this time until his operation in May, 1942.

In July, 1941, he began to vomit, and in August, 1941, he was usually bringing up a pint or two of vomit about every third day, with considerable relief to the epigastric pain, which was now very frequent and usually occurring about $1^1/_2$ hours after food. Some relief was obtained with magnesium trisilicate.

In November, 1941, the vomiting was more severe and, as the months passed, became a more and more prominent feature of the illness. At this time the patient was taking sodium bicarbonate to relieve his symptoms. Later he used MacLean's powder in doses of 1 or 2 drachms each day and obtained some relief.

Patient took a very intelligent interest in his condition and began to doubt if he could much longer conceal his true state of health. He made a daily record of vomiting.

1941						
November 11–30	..	Vomited	10	out of	10	days
December	.. ..	,,	17	,,	31	,,
1942						
January	.. ..	,,	21	,,	31	,,
February	.. ..	,,	21	,,	28	,,
March ..	.. ..	,,	21	,,	31	,,
April ..	.. ..	,,	23	,,	30	,,

In April, 1942, patient was vomiting two or three times a day on most days and often in the night too. It is not surprising that he complained of cramps in April, the first occasion when this symptom was present. The cramps appeared in the calves, feet, and toes. They never occurred in the day but only in bed and often wakened him from sleep. In May, 1942, the vomiting was even more severe and after every meal and consisted of several pints of acid fluid mingled with semi-digested foodstuffs.

Cramps were now experienced in the hands as well as in the feet. Patient was, at this stage, much emaciated and dyspnœic on the slightest exertion.

On May 17, 1942, he made this note in his diary: "Vomiting occurs after breakfast and after lunch, but in the afternoon and evening and during the night nothing at all can be kept down but is rejected within half an hour of ingestion." Thirst was now a severe symptom.

During the week preceding admission patient noted that the amount of urine was getting very small, and he learnt from his wife afterwards that from 9 A.M. on May 23 to his admission on May 24 he did not pass any urine at all. He was admitted in a deplorable state, a mere skeleton, emaciated and dehydrated so that bony prominences looked like perforating the thin parchment-like skin.

COMMENTS

The semiconsciousness associated with a seizure and albuminuria raised the question of uræmia. On the other hand, the generalised board-like rigidity (which resulted from the muscular spasm of tetany) and diminished liver dullness (probably from dilatation of the stomach) gave rise to a preoperative diagnosis of generalised *peritonitis*.

The reason for secrecy and avoidance of treatment lay in the fact that the patient expected to lose his job if he went sick with "gastric trouble" again. He held out until alkalosis, tetany, and coma overcame him.

After operation a fractional test-meal showed the presence of hydrochloric acid in the stomach, and it is evident that the alkalotic tetany resulted both from the loss of hydrochloric acid and the ingestion of large amounts of alkaline stomach powders (see above). Under war-time conditions it was unfortunately impossible to make full biochemical investigations before operation.

SUMMARY

A case of advanced pyloric stenosis is described in which persistent and severe vomiting brought about alkalosis, tetany, and coma. The patient completely recovered after operation.

I wish to thank Surgeon Vice-Admiral H. C. Colson, C.B., C.B.E., D.P.H., Medical Director-General, Royal Navy, for permission to publish this case.

Reviews of Books

Lectures on the Liver and its Diseases

H. P. HIMSWORTH, M.D., F.R.C.P., professor of medicine in the University of London, and director of the medical unit, University College Hospital, London. Oxford: Blackwell Scientific Publications. 1948. Pp. 204. *18s. 6d.*

Professor Himsworth begins by reviewing the types of liver damage produced in animals by dietary means, by poisons, and by interference with the circulation. Of particular interest is the importance he attaches to local vascular factors in determining the distribution and extent of hepatic lesions. His cardinal point is that the pathological sequence of events depends not so much on the nature of the causative agent as on the anatomical form of the initial injury.

This concept he then applies to the classification and interpretation of human liver disease. Here the question arises whether dietary deficiency can cause liver injury in man as it does in animals. Professor Himsworth believes that it can: he suggests that the fatty liver of alcoholism and the hepatic necroses of pregnancy are both essentially effects of malnutrition, and he cites the observations of Trowell, the Gillmans, and others in the tropics to show that in malnourished populations a human parallel can be found to each of the types of liver injury that have been produced experimentally by diet. On such evidence he proposes a broad ætiological classification of human liver disease into two groups—toxipathic and trophopathic hepatitis. The distinction is systematic rather than practical, and may be premature, but it will have served its purpose if it draws the attention of the general reader to a possibly unfamiliar field. The investigations in Africa undoubtedly have a significance far beyond the sphere of purely tropical disease, and Professor Himsworth was one of the first to recognise this.

The last chapters are concerned with the symptomatology of hepatic failure, and the clinical course of the syndromes whose pathology has been described. This is more familiar ground, but most readers will find something to learn.

The book has many omissions; but it is a series of lectures, not a textbook. In these days it takes courage, in a work of this kind, to dispense with a recapitulation of physiology and biochemistry, and to devote only a single page to laboratory tests and aids. Such a treatment inevitably produces an effect of onesidedness, but it has the advantage of throwing into clear relief the author's own line of thought. At times too little attention seems to have been given to the work of others—for instance of Sebrell and his colleagues, and of Bollman. In places, too, the argument is finely drawn and over-ingenious. But Professor Himsworth does not claim to do more than put forward tentative hypotheses, which, he says, must be submitted to repeated and rigorous criticism. Taken in this sober spirit, the book is a valuable contribution to medical science. It is also, in a sense, a work of art, for it shows an unusual blending and harmony of the intellectual approach of the bedside with that of the laboratory.

Modern Trends in Ophthalmology

Vol. II. Editor: ARNOLD SORSBY. London: Butterworth. *1948. Pp. 600. 63s.*

IN order to give a true picture of the direction in which ophthalmologists are working, the editor of this popular book, now in its second edition, has rightly cast his net wide: of the 44 contributors 27 are from outside the British Isles, and he has even succeeded in enlisting the coöperation of Moscow. Among so many contributors of international repute it is hard to pick and choose, but it is pleasant to see recognition of the work of Ragnar Granit on the electrophysiology of the retina, and of Stina Bjork on hypertensive retinopathy, both contributions coming from Sweden. A summary of his work on gonioscopy is given by Troncosa of Columbia University, and this is of special interest now that the use of the gonioscope has come to be recognised as an essential diagnostic procedure in glaucoma. Arruga, one of the world's authorities on retinal detachment, gives his latest views on this subject, and Waardenburg contributes a chapter on inheritance in ophthalmology. Professor Sorsby himself writes on several issues—X-ray measurement of the diameters of the living eye, virus infections, penicillin, and the use of amniotic membrane in eye burns. The book is outstanding.

Sulfonamides and Allied Compounds

ELMORE H. NORTHEY, PH.D., administrative director, Stamford Research Laboratories, American Cyanamid Co., Connecticut. New York: Reinhold Publishing Corporation; London: *J. & A. Churchill. 1948. Pp. 660. 75s.*

THIS is one of the Chemical Monographs in the well-known series produced under the auspices of the American Chemical Society. It attempts to cover the chemical side of the sulphonamide group and also to provide pharmacologists and clinicians with data concerning chemotherapeutic activity, as well as references to other important information on properties. Some idea of its scope can be gauged from the fact that it contains 2608 references, of which 599 are to chemical literature.

The chemical aspect, indeed, occupies most of the book. After a succinct and accurate historical introduction, in which justice is done to British and French workers, the pharmacology and toxicology of the sulphonamides are well described, and there are interesting accounts of the theories of the mechanism of action and of drug-resistance. The clinical section, occupying some 60 pages, is largely an uncritical review of published papers; but, as Dr. Northey says, "*it is necessary that* those who are engaged in the long experimental approach of launching a new drug have some knowledge of the criteria on which the fruits of their labours will be judged." He has provided the most complete existing survey of the literature of the sulphonamide drugs, and has enabled any chemist who is ambitious to synthesise a new sulphonamide to see at a glance what ground has already been covered.

THE LANCET

LONDON: SATURDAY, AUGUST 7, 1948

A Compromise?

CONSULTANTS and specialists must have a central dy to represent their interests in the National alth Service, and three proposals have been made this end.[1] The first is that a new and independent ganisation should be formed by direct election of presentatives to regional committees which in turn ould elect a central council with its own secretariat. ch an organisation would have to start from scratch, d there is at present no sign of the determination eded to overcome this handicap. The second and ore realistic proposal is that the representation of ecialists, as of general practitioners, should be trusted to the British Medical Association. But this o has its difficulties. Possessing their own ancient stitutions, specialists have not in general been in e habit of looking to the B.M.A. for guidance, and y no means all of them share its confidence in the adership it offers. They note that, though they are ow accorded "autonomy" within the association, he presentation of their views may ultimately depend n the approval of a council on which the general ractitioner, by right of numbers, will always have he chief voice. One of the weaknesses of the B.M.A. as been that its representatives derive their authority rom local meetings which are often poorly attended; and in this case a further distorting factor will be ntroduced if a large proportion of the heads to be ounted are those of part-time specialists. The ilution of specialist labour which the National Health Service makes necessary should not be allowed to lead to a lowering of standards, of which the colleges have long been the guardians: and there is a real risk that it might do so. With all this in mind, many feel that, despite improvements, the B.M.A.'s consultants' and specialists' committee remains constitutionally unsuited to perform some of the functions it seeks to assume. Its lack of professional weight serves indeed to display certain contrasting advantages in the third proposal, under which the affairs of specialists would be entrusted to a central council of tripartite composition, drawing its representatives partly from the colleges, partly from the specialist associations, and partly from the regions. Ideally arranged, this would give the specialist three forms of representation—first through his college, secondly through his technical association, and thirdly through his region (perhaps on a postal vote). The resultant body would command the more respect, both inside and outside the profession, in that it could speak with these three kinds of authority. The serious fault of the pilot model set up on June 14 was that the confusing situation prevented full representation from the regions

As will be seen from the announcement on p 239, a compromise is now suggested by which a comparatively small committee "to advise the Minister of Health on all matters concerning consultants and specialists" would be established jointly by the Royal Colleges, the Royal Scottish Corporations, and the British Medical Association. The B.M.A.'s committee, and the colleges' committee, would both remain in existence "to brief the joint committee," and the joint committee would allocate, as soon as practicable, fields in which its constituent bodies were "free to take independent action and to deal with governmental bodies direct." Actually, the different aspects of consultant and specialist work are so closely connected that it is not easy to see how the functions of the two "briefing" committees could be separated without giving one or other the lion's share But if under Sir LIONEL WHITBY's chairmanship a reasonable and fair division of labour can somehow be achieved, the compromise will be welcome. We have to ensure equally that the best traditions of consultant practice are preserved and that every specialist is represented and helped in the manner he would prefer.

Food and the Liver

IN animals experimental deficient diets have produced two distinct types of hepatic lesion—namely, fatty infiltration and massive necrosis.[1,2] Fatty infiltration, if sufficiently severe and long-continued, gradually develops into a diffuse fibrosis resembling Laennec's cirrhosis: massive necrosis, if not quickly fatal, tends to heal with nodular hyperplasia and scarring.[2]

There is fairly general agreement that the nutritional defect responsible for the fatty infiltration is lack of choline, or of substances containing labile methyl groups which the body can utilise for choline synthesis: but the mechanism by which fatty infiltration leads to cirrhosis remains more doubtful. There is, however, some evidence that the integrity of the liver cells, as of other cells, depends on a balance between their metabolic demand and their nutritional supply. Thus MCIVER and WINTER[3] have shown that a degree of anoxia which is well withstood by normal rats will produce centrilobular zonal necrosis in rats whose metabolic rate has been raised by injections of thyroxine. Similarly, a dose of thyroxine which by itself causes no demonstrable hepatic injury will greatly enhance the toxicity of carbon tetrachloride,[4] a drug whose hepatotoxic action has lately been ascribed to the reduction in the intralobular circulation that follows its administration.[5] A similar impairment of the intralobular circulation is seen in fatty livers, as a result of sinusoidal compression by the fat-laden liver cells,[6,7] and HIMSWORTH and GLYNN[2] suggest that this leads to malnourishment of the centrilobular cells, which therefore undergo atrophy followed by fibrous replacement and consequent cirrhosis. Hypothyroidism, induced either surgically or chemically, lowers the metabolic activity of the liver cells, thereby enabling them to survive an

otherwise lethal degree of circulatory insufficiency; and, as HANDLER[8] has shown, hypothyroidism gives protection against fatty cirrhosis even though it increases the amount of fat in the liver.

Opinion differs more widely about massive necrosis. By means of diets deficient in thio-amino-acids some workers produce this condition consistently, others only occasionally, and others (using ostensibly the same technique) not at all. Variations in strain susceptibility, in the nature of the yeast and vitamin supplements, in the intestinal flora, and in climatic conditions are relevant factors, summarised by RAO[9] and awaiting elucidation. The irregularity of the results obtained in different experiments, and particularly in different laboratories, strongly suggests that an infective agent is also playing an important part; but neither GYÖRGI and GOLDBLATT[1] nor HIMSWORTH and GLYNN[2] could find any evidence of such an agent, either by culture, animal passage, or epidemiological studies. One notable difference, however, between diets which have caused necrosis and similar diets which have not done so is the presence in the latter of a supplement of vitamin E. Though SCHWARZ[10] previously called attention to the value of tocopherol as a protective agent against hepatic injury, GYÖRGI[11] was the first to establish that massive necrosis cannot be produced dietetically in rats unless the diet is deficient in vitamin E. He thinks that "as a further nutritional factor the quality of dietary fat should probably be taken into consideration."

In man, as in animals, it has been easier to demonstrate a relation between diet and fatty cirrhosis than between diet and massive necrosis. The work of TROWELL[12] in Uganda, the GILLMANS[13] in South Africa, and WATERLOW[14] in the West Indies, and of many others, has drawn attention to the remarkably high incidence of hepatic disease in badly nourished people in widely separate parts of the world; and, though parasitic infections are partly responsible for this damage to the liver, the response to nutritional therapy leaves little doubt that nutritional deficiency is usually the major factor. Further suggestive evidence to this effect is given in our present issue by Professor FERNANDO and his colleagues in Ceylon, who recognise two types of cirrhosis—a "toxic cirrhosis" following acute or subacute massive necrosis, and a fine diffuse fibrosis, or Laennec's cirrhosis, following fatty infiltration. A significantly high proportion of all their cirrhosis cases had subsisted for a year or more on a diet grossly deficient in protein, especially animal protein; but their data do not make it possible to relate the two types of cirrhosis to different types of diet. Since in nature a diet deficient in lipotropic factors is usually deficient in thio-amino-acids, and vice versa, it seems probable that in these patients the onset of massive necrosis is determined not by a specific dietary deficiency but by some extraneous factor such as an attack of infective hepatitis. It is clear, too, that in some malnourished populations, as in some animal experiments, the incidence of hepatic lesions is surprisingly low.[15]

Nevertheless, it would be a grave error to conclude from this that nutritional factors are of little moment In massive hepatic necrosis multiple nutritional factors are concerned, of which at least two have already been defined, and there can be little doubt that relative as well as absolute deficiency is of great importance. HIMSWORTH and GLYNN,[2] for example, found that, whereas hepatic necrosis developed when the total daily intake of casein per rat fell below 500 mg., it was not seen when the intake was further reduced below 200 mg. Similarly, a small supplement of milk given to rats maintained on a diet of mealy pap precipitates their death with extensive liver lesions[16]—a finding possibly connected with the growth-stimulating effects of small protein supplements, and the consequent diversion to other tissues of factors essential for normal liver metabolism. Though we cannot yet account for these apparently anomalous findings, it is already certain that the integrity of the liver depends very largely on nutrition.

Population Pressures

THE threat of war and starvation in this tightly packed island led many speakers in a recent House of Lords debate to urge the imperial dispersion of our population. In so far as it would mean selective emigration of the young and the fit, this policy has obvious dangers, not only for this country but also for the whole British Commonwealth, whose strength partly depends on our maintaining in Britain a well-balanced working force not too much encumbered by aged dependants. To this end we must achieve at least a balance between the death-rate and the number of children surviving to adulthood. Here the measure of success is the net reproduction-rate, which summarises the trend of movement as in a kaleidoscopic sequence: a net reproduction-rate of 1·00 means that at prevailing birth and death rates, 100 women will be replaced by 100 of their daughters surviving to child-bearing age in the next generation Only from such data can any long-term demographic predictions be made; but we need no refined techniques to know the extent of the short-term problem of population structure. The numbers of new young entrants to industry available in 1950 has been already decided by their births in 1934; except by migration, their numbers are unchangeable. The figures show that the age pyramid has in fact already become top-heavy, and it is evident that any precipitate removal of the young might be disastrous. Our position is shared, of course, by many of the countries encompassed by Western Union. Two reports from the World Health Organisation,[17] which give details of the shifting balance of births and deaths in many countries, show that France's situation, for example, is even more critical than ours, since she has already reached the stage of decline in population. On the other hand the trend of her net reproduction-rate, which reached a nadir of 0·77 in 1941, has latterly been reversed, and there is hope that a balance

struck between deaths and replacements will put France into the low stationary phase, where, as in the United States, most of Western Europe, and the British Dominions, low birth-rates are matched by low death-rates to keep the population stable in numbers.

Preoccupation with the immediate difficulties of replacement in Western Europe should not blind us to the broader picture of the movements and pressures of population in the world at large. BLACKER[18] describes how, in the last thousand years, the small European centre outstripped the rest of the world in technical achievement. Exploration and colonisation spread the European stock over the Americas, Africa, and the East: indeed in North America what WOODROW WILSON called the "swarming of the English" resulted in an eleven-fold increase in the population. A high birth-rate combined with falling death-rates to produce in both colonisers and subject peoples the early expansive phase of population growth. The checks and balances of epidemic and famine, operating as in modern China with its equally high birth and death rates and stable population, were obliterated by advances in agricultural and sanitary science. These effects persist among the peoples of India and Indonesia; but a new demographic stage appeared in the centres from which these colonising influences came. Industrialisation and urbanisation in the "advanced" countries of Western Europe were accompanied by closing of the gap between birth and death rates, and even, in the middle 1930s, by the stage of declining numbers. Areas of low fertility formed and grew steadily wider until, just before the second world war, the trend altered and an increase in the birth-rate set in. The late war certainly did not arrest this reversal, and most Western European countries now have higher hopes of demographic stability. In Eastern Europe, particularly in the Soviet Union and in Japan, there exists a different state—one of late expansion, where the death-rates are declining more quickly than the birth-rates and population increase continues. In the Mohammedan world, breeding to capacity continues but the high death-rates hamper numerical increase. Vital statistics in the Middle East, as in India and Indonesia, are rather unreliable; in India, for example, the village chowkidar is notoriously selective in recording births and deaths. Yet it seems clear that among the mixed blessings derived from a contact with Western civilisation has been a decrease in death-rates and a resultant expansion of the already teeming millions of South-East Asia.

These facts raise questions of material and moral importance. The pressure of population and the demand for *Lebensraum* has long been held to be a potential cause of war; and in war the position of the relatively infertile Western European appendage to the great land mass of Eurasia is unenviable. Again, the new food morality preached by SIR JOHN BOYD ORR, whereby each country receives a slice of world's food cake in proportion to its human needs rather than to its economic purchasing-power, may have serious repercussions in this country. Even our present dietetic standards are princely compared with the bare subsistence of the Indian peasant, and any strict egalitarianism would, BLACKER suggests "keep our wives and perhaps our daughters standing in queues for many years to come." But, as ORR would no doubt point out, we have defied Malthusian prophecies thus far, and the science of food production and distribution is still in its infancy. Beyond a certain point too, demography ceases to be an exact science. Long-term population forecasts which (said STOWMAN) "are made with impunity only because no-one reads them ten years after they are published," are often little better than educated guesses. All turns on the emancipation and education of women in countries where over-population may be the prelude to war. Through them, the contraceptive limitation of families may balance the death-diminishing powers of sanitary progress, and relieve both their own arduous lives and the pressing demands of too many hungry mouths.

Annotations

THE FIRST MONTH

DOCTORS and patients have now had a whole month in which to sample the advantages, disadvantages, and shortcomings of the National Health Service. Most practitioners would agree, we believe, that the month has brought fewer changes than they feared. It is true that, for many of them, surgeries have been unusually heavy: but some of the extra work will not have to be repeated. Patients uncertain of their rights, or how to obtain them, have come to ask questions, or to hand in forms. Others have waited for July 5 before presenting themselves to have their eyes tested, or their minor operations arranged. Private patients who formerly had repeat prescriptions filled by pharmacists now come to have each prescription written on to the official form: but in course of time this additional labour will be reducible by prescribing, in some of the cases, medicine of a type or quantity that will demand less frequent repetition.

Administratively the initial stages proceed steadily and with surprisingly few hitches. The final count of doctors joining the service will not be known until allowance can be made for those whose names now appear on the lists of more than one executive council, and for those who have joined the service to secure their right to compensation, but who for reasons of age or infirmity, or because they now intend to specialise, will soon be retiring from general practice. Even now, however, it is safe to say that enough doctors have joined to provide in all areas an adequate service. The patients have not been backward in completing their application forms, and the number of patients on doctors' lists is already said to approach 90% of the population. The cards have come in quickly and many an executive council office has found it hard to keep pace with its inordinately heavy daily intake. Some delay is inevitable while patients' cards are sorted, counted, and recorded, and one cannot expect the new record cards to arrive immediately after dispatch of the application forms. What is less excusable is that stocks of prescription and certificate forms received by executive councils before the appointed day have sometimes been insufficient to meet the practitioners' needs, and that schemes are announced for opting out of superannuation, and for claiming compensation, before executive councils possess the memoranda and application forms that will enable practitioners to make their claims.

The rapid enrolment of so high a proportion of the public has only too quickly revealed the uneven distribution of doctors. Reports from some under-doctored otherwise lethal degree of circulatory insufficiency; and, as HANDLER[8] has shown, hypothyroidism gives protection against fatty cirrhosis even though it increases the amount of fat in the liver.

Opinion differs more widely about massive necrosis. By means of diets deficient in thio-amino-acids some workers produce this condition consistently, others only occasionally, and others (using ostensibly the same-technique) not at all. Variations in strain susceptibility, in the nature of the yeast and vitamin supplements, in the intestinal flora, and in climatic conditions are relevant factors, summarised by RAO[9] and awaiting elucidation. The irregularity of the results obtained in different experiments, and particularly in different laboratories, strongly suggests that an infective agent is also playing an important part; but neither GYÖRGI and GOLDBLATT[1] nor HIMSWORTH and GLYNN[2] could find any evidence of such an agent, either by culture, animal passage, or epidemiological studies. One notable difference, however, between diets which have caused necrosis and similar diets which have not done so is the presence in the latter of a supplement of vitamin E. Though SCHWARZ[10] previously called attention to the value of tocopherol as a protective agent against hepatic injury, GYÖRGI[11] was the first to establish that massive necrosis cannot be produced dietetically in rats unless the diet is deficient in vitamin E. He thinks that "as a further nutritional factor the quality of dietary fat should probably be taken into consideration."

In man, as in animals, it has been easier to demonstrate a relation between diet and fatty cirrhosis than between diet and massive necrosis. The work of TROWELL[12] in Uganda, the GILLMANS[13] in South Africa, and WATERLOW[14] in the West Indies, and of many others, has drawn attention to the remarkably high incidence of hepatic disease in badly nourished people in widely separate parts of the world; and, though parasitic infections are partly responsible for this damage to the liver, the response to nutritional therapy leaves little doubt that nutritional deficiency is usually the major factor. Further suggestive evidence to this effect is given in our present issue by Professor FERNANDO and his colleagues in Ceylon, who recognise two types of cirrhosis—a "toxic cirrhosis" following acute or subacute massive necrosis, and a fine diffuse fibrosis, or Laennec's cirrhosis, following fatty infiltration. A significantly high proportion of all their cirrhosis cases had subsisted for a year or more on a diet grossly deficient in protein, especially animal protein; but their data do not make it possible to relate the two types of cirrhosis to different types of diet. Since in nature a diet deficient in lipotropic factors is usually deficient in thio-amino-acids, and vice versa, it seems probable that in these patients the onset of massive necrosis is determined not by a specific dietary deficiency but by some extraneous factor such as an attack of infective hepatitis. It is clear, too, that in some malnourished populations, as in some animal experiments, the incidence of hepatic lesions is surprisingly low.[15]

Nevertheless, it would be a grave error to conclude from this that nutritional factors are of little moment. In massive hepatic necrosis multiple nutritional factors are concerned, of which at least two have already been defined, and there can be little doubt that relative as well as absolute deficiency is of great importance. HIMSWORTH and GLYNN,[2] for example, found that, whereas hepatic necrosis developed when the total daily intake of casein per rat fell below 500 mg., it was not seen when the intake was further reduced below 200 mg. Similarly, a small supplement of milk given to rats maintained on a diet of mealy pap precipitates their death with extensive liver lesions[16]—a finding possibly connected with the growth-stimulating effects of small protein supplements, and the consequent diversion to other tissues of factors essential for normal liver metabolism. Though we cannot yet account for these apparently anomalous findings, it is already certain that the integrity of the liver depends very largely on nutrition.

Population Pressures

THE threat of war and starvation in this tightly packed island led many speakers in a recent House of Lords debate to urge the imperial dispersion of our population. In so far as it would mean selective emigration of the young and the fit, this policy has obvious dangers, not only for this country but also for the whole British Commonwealth, whose strength partly depends on our maintaining in Britain a well-balanced working-force not too much encumbered by aged dependants. To this end we must achieve at least a balance between the death-rate and the number of children surviving to adulthood. Here the measure of success is the net reproduction-rate, which summarises the trend of movement as in a kaleidoscopic sequence: a net reproduction-rate of 1·00 means that at prevailing birth and death rates, 100 women will be replaced by 100 of their daughters surviving to child-bearing age in the next generation. Only from such data can any long-term demographic predictions be made; but we need no refined techniques to know the extent of the short-term problem of population structure. other countries—Greece, Yugoslavia, Italy, and Poland—and he reminds his readers of the Allied agreement that Germany should not be better fed than the Allied nations. Significantly, he adds that there is little opportunity to read the truth about the present state of nutrition in Germany, and suggests that this is kept out of the papers in order to prevent public alarm.

In this light it seems doubly unfortunate that last October's report by the Combined U.S.-British-French Nutrition Committee has not been made public. In reply to a question in the House of Commons, Mr. C. P. Mayhew,[3] speaking for the Foreign Secretary, quoted this report as saying that nutrition of the urban population in the Western Zones had improved in the previous six months, that famine œdema was very rare, and that the weight of adults had not declined. Why were the Germans not told this? Similarly, the recent official report on the incidence of tuberculosis in the British Zone should receive the widest publicity. We trust that there will be no concealment of the findings of the bipartite nutrition survey committee which in April toured the British and American Zones. As Dr. Wolff-Eisner's conclusion clearly shows, suppression of the facts makes the people think that there is something to hide.

THE PAY OF A STUDENT NURSE

On July 5, when nurses began to contribute some £18 a year to National Insurance, the payment received by a first-year student nurse fell from £55 a year to £37 4*s*. 8*d*., and hence to the monthly sum of just over £3. Those in the later years of training were a few shillings a month better off. A group of six or seven hundred nurses, drawn from St. Mary's Hospital, Plaistow, Whipps Cross Hospital, the Prince of Wales's Hospital, Tottenham, and other institutions threatened to resign on Aug. 1 unless their claims for higher pay were officially considered. To help to allay their anxiety the Ministry of Health announced that a final recommendation of the Rushcliffe Committee—that student nurses should have an additional £15 a year—had been accepted and was to come into force forthwith; but this ill-timed announcement of an already agreed plan was mistaken for a niggardly concession, and has merely roused the students further. For the rise still leaves them poorer by some £3 a year, though they will be now entitled to benefits which they could not previously command. On July 27, at a meeting convened by the Confederation of Health Service Employees, at Canning Town, student nurses called upon the Functional Council to proceed with negotiations for a £5 a week wage for them; according to the *Times* of July 28 the meeting was attended by nurses from more than a dozen London hospitals. This seems to indicate a growing dissatisfaction, since at the original meeting, on July 22, the general feeling is reported to have been in favour of an increase of £50 a year.

It is stimulating to find nurses—who usually seem too busy or too tired for polemics—taking an active line for once. Many will sympathise with their protest, especially since—in the best traditions of their profession—they are prepared to stay at work for a time after Aug. 1 in order to give the hospitals a chance of getting new staff. Over a year ago a correspondent[4] in our columns outlined the following budget for a student nurse receiving £55 a year: £20 for essential clothing other than uniform (including underwear, stockings, shoes and shoe repairs, as well as outdoor clothes); £25 for expenses when off duty, including fares and modest entertainments; and £5–£10 for insurance and superannuation (as the cost ran then); leaving £5 for petty items such as cigarettes, tooth-paste, small repairs, Christmas presents, hairdressing, and textbooks. This narrow budget has become even more stringent in the months which have passed since then: for example, clothing cannot be covered within the prescribed limit, especially as some items, such as shoes and stockings, are the nurse's contribution to her uniform and suffer heavy wear; and shoes are now particularly costly. Even a light smoker pays heavily for the privilege; fares have risen; and almost all small expenses have increased. These items are hardly offset by the saving of £5–£10 for insurance and superannuation—now covered, of course, by the National Insurance contribution of £18. In short, to meet all their expenses student nurses must have some help from home; and many of them inevitably come from homes where the parents feel that the grown child should be a contributor, not an expense.

Our contributor thought, in February, 1947, that there was a good case for giving all student nurses a maintenance grant at a flat rate of £100 a year throughout training. At that time, however, the long-standing objection could be made that the more the hospitals paid their student nurses the more they would exact in service and the less they would regard them as students. Now, the position is changed. The contract of the nurse is no longer with the hospital but with the regional hospital board; and though her pay comes to her through the hospital management committee, it actually derives from the regional board by way of the block grant. The hospitals are thus no longer in a position to feel that they "employ" their nurses; while the nursing subcommittees of the regional boards will doubtless take a responsible part in raising and maintaining student status. A fresh study of the pay of student nurses is urgently needed; but it is specially unfortunate that their claims have been so neglected and mismanaged that they have been driven to forcible protest. An emergency meeting of the Whitley Councils' Nurses' and Midwives' Functional Council has been called for Aug. 20 to consider the position, but a reassuring interim measure of some kind would be welcome.

THE CEREBELLUM RECONSIDERED

UNTIL lately the cerebellum has been the most baffling part of the central nervous system. Though its removal produces grave motor incapacity it is largely unresponsive to electrical stimulation; and it is only in the past year that its function has been shown to be as precisely localised as that of the motor cortex.

When Dr. John Fulton, professor of physiology at Yale, spoke about the cerebellum at the National Hospital, Queen Square, on June 11, he laid stress on the relation between the mode of stimulation in the central nervous system and the response evoked. Wyss and Obrador found that there was a difference in the optimal duration of stimulation of the motor area of the cerebral cortex for proximal and distal muscles. Indeed, this optimal duration varied for contiguous muscles, and not only the duration of stimulus but its shape and frequency will modify the resulting cortical activity. This is true for area 4 and area 6, and the mode of stimulation seems to be even more important for those parts of the cortex from which autonomic activity can be evoked than for those representing voluntary movements. Stimulation of an area anterior to the motor cortex from which eye movements can be evoked will cause conjugate deviation of the eyes to the same side or to the opposite when the frequency of stimulation is changed. Then there is an area of the cerebral cortex, in the same region as that which induces conjugate deviation of the eyes, where stimulation results in the motor activity of the "waking state" and the "sleeping state." Thus, two opposite forms of activity can be induced at will by applying stimuli of different frequency to the same area. Professor Fulton had the experience of invoking the

4. *Lancet*, 1947, i, 190.

areas tell of doctors with lists already more than saturated, while from others come reports of groups of doctors faced with unexpectedly small lists, and shrinking incomes, spontaneously approaching the newly formed Medical Practices Committee with requests that their particular area shall be declared over-doctored, and closed to the entry of further practitioners. Evidently the committee's purpose, as well as its personnel, has been tacitly accepted, and it has quietly embarked on its tasks. It has delegated considerable power to the executive councils over such matters as the sanctioning of the employment of assistants, and the admission of new principals, only asking to be specifically consulted in a short schedule of cases where permission might well need to be withheld.

The local obstetric committees, too, have begun work in most areas. For the most part they are interpreting their mandate leniently, and refusing permission to few doctors who have signified their willingness to accept midwifery responsibilities. Allocation committees have so far had very few cases to deal with—surprisingly few when one considers the very large numbers of patients (over 18 million) who have sought to be freshly included in doctors' lists in these few short weeks. The fact that these cases have been so few goes far to show that the complaints of doctors refusing for all manner of reasons to accept certain patients, to which so much prominence has been given in the press and in Parliament, cannot concern more than a small minority of doctors.

Patients have been confused. In particular, the simultaneous launching of a National Health Service, participation in which is optional, and a National Insurance scheme, compulsory under penalty for most families, has led to every permutation of misunderstanding. But it does now seem that the relatively high rate of weekly insurance contribution which has become payable has been the determining factor which has decided so many to enter so quickly. Conversely, a remarkably high proportion of elderly people have said that, as no direct weekly contribution is being asked of them, they feel it unfair to avail themselves of the benefits to which they are entitled. It is probable that many who so far have not signed cards will do so if in the ensuing months they need medical care. The fact that medicines cannot be supplied at the expense of the service to any but enrolled patients has brought many, and will continue to bring others, into the service. It will be surprising if the estimated 98% of acceptances in the first two years is not reached long before this term is up.

July began with very unseasonable weather which did nothing to improve the health or the temper of the British public. The incidence of infectious illnesses, too, seemed somehow to linger on this year, and the load of measles, mumps, and chickenpox remained greater than usual. Nevertheless, we have got through the first month without undue disturbance, and the months that follow should allow the new service to get well into its stride before it has to bear the burdens of winter.

A SCRUTINY OF MENTAL HEALTH PROBLEMS

AGGRESSION, world citizenship, and guilt are the themes of the three international conferences embodied in the International Congress on *Mental Health*, to be held from Aug. 11 to 21 at the Central Hall, Westminster. For this congress, organised by the National Association for Mental Health at the request of the International Committees on Child Psychiatry and Mental Hygiene, and the International Federation for Medical Psychotherapy, some 2000 delegates, drawn from nearly 50 countries, have registered. About 900 delegates are coming from abroad, and only Soviet Russia, among the great powers, has failed to send any.

An unusual plan of preparation has been followed: for some months past nearly 300 groups of people, including psychiatrists, doctors, psychologists, social workers, clergy, lawyers, and others have been at work in more than 20 countries examining questions which are to be considered at the congress. Reports of their investigations have been sent to the organising committee in London, where they have been edited for consideration by an international preparatory commission. This commission, composed of 30 leading people in the mental health field from various countries, will meet at Roffey Park, Sussex, for a fortnight before the opening of the congress, to read the reports and decide which aspects of them should be considered further at the congress.

The main purpose of the three conferences is to study group relations in the community, in industry, and between nations. It is, perhaps, from such studies that we shall at last achieve the ability to live at peace in a small and crowded world.

GERMANY'S FOOD

How much food are the Germans eating today? This question has had the attention of many trained observers, but their answers are no more than conjectures since the scale of rations bears little relation to the amount of food consumed. Some months ago Dr. Aschoff,[1] a German nutritionist, told us that between last November and February the rations might yield as little as 866–1135 calories a day. But these figures take no account of unrationed food or of rationed foods from the black market, which in Germany is many times more active than any we have known in Britain. By some this black market has been actually defended; for the time being, it is argued, there is not enough productive work for the population, and the two or three days spent each week in foraging for supplies averts the trouble usually said to come from idle hands and brains. Nevertheless, there are ample reasons for not regarding such a situation as satisfactory. Any black market is acutely competitive: without money to buy or goods to barter the customer goes without, and many city-dwellers are physically incapable of getting to the farms where the market chiefly thrives. Moreover, the effect on the German mind of the present slender official rations must also be considered. Naturally the Germans are preoccupied with the rationing restrictions because of their comparative novelty and their severity; and naturally, too, as a defeated people, they seek to circumvent a system which may seem to be imposed by their conquerors. The danger now is that isolation, frustration, introversion, and self-pity, reinforced by the meagreness of the official rations, by rumour, and by false propaganda, will establish a myth that the population was deliberately starved after the second world war. One example of this propaganda is to be found in German reports of gross increase in the incidence of tuberculosis—an increase not substantiated by competent outside observers.[2] How rumour may take root is shown again in Dr. Wolff-Eisner's recent book, of which an account is given on p. 228. His integrity in describing the conditions of starvation and neglect which he saw and suffered at Theresienstadt concentration camp is beyond dispute; and no doubt he brings the same honest intention to bear on his later passages where he suggests that conditions in Germany today are not much better than in the camp. This contention, however, is supported only by reference to the publications of other German doctors in which the possible effects of inadequate nutrition are described in general terms, and by rumours of conditions in Hamburg and Düsseldorf. Unlike most Germans, Wolff-Eisner shows awareness of the post-war plight of

ISSUE OF APPLIANCES

Arrangements under the Act

General practitioners may prescribe for their patients the appliances scheduled in the appropriate regulations. Other medical and surgical appliances are provided through the hospital service in which any appliance considered necessary may be prescribed. In general, appliances will be issued free: but in the case of spectacles, artificial limbs, and dentures, certain more expensive alternatives approved by the Minister will be issued on payment of the extra cost. Repairs and replacements will be made without charge except where the need has arisen through the patient's carelessness. In the case of spectacles for pupils whose medical care is the responsibility of the local education authority, any charge is to be recovered, not from the pupil, but from the authority.

OPHTHALMIC SERVICES

Normally, a patient wishing to obtain spectacles, whether or not he already has a pair, must obtain a note from his family doctor, who need not necessarily be on the local executive council's list. Provision is made for patients who are "unable or are unwilling on conscientious grounds" to get a doctor's certificate; these are to get in touch with the executive council.

Having obtained a note from his doctor the patient may then attend either an ophthalmologist or an ophthalmic optician. No doctor's note is needed for subsequent visits.

If glasses are required, the prescription is sent through the post; and the patient then chooses an ophthalmic or dispensing optician from whom to obtain them. The Ministry's schedule allows for the free issue of the following types of lens: spherical, cylindrical, or sphero-cylindrical, prisms, tinted, lenticulars, and, when clinically necessary, bifocals. Meniscus or toric lenses, or equivalent forms, and a wider range of frames are listed as obtainable on payment by the patient of the extra cost. As regards replacements and repairs, part of the cost, in the case of these special lenses and frames, will be borne by the patient; and if the need has arisen through carelessness the patient will always pay the whole cost.

The supplementary ophthalmic service is to be replaced by the permanent hospital ophthalmic service as soon as this can be built up. In the meantime boards of governors and management committees are urged to appoint dispensing opticians, on either a whole-time or a part-time basis; and, on behalf of hospitals, the Ministry's supplies division are to negotiate contracts with manufacturers and prescription houses. Patients who obtain their prescriptions at a hospital are at liberty to take them to an outside ophthalmic or dispensing optician; and in this event the optician recovers his charge from the hospital.

Artificial eyes are to be provided exclusively by the hospital service, and will be prescribed by ophthalmologists. Acrylic eyes are made by the Ministry of Pensions, which is able to supply these at short notice; and hospital committees and boards are advised to notify this Ministry's chief regional officer when the attendance of a fitter is required. In difficult cases a special eye will be made from a cast, at the Ministry's optical appliances depot. Contracts are being placed with firms for the supply of artificial eyes.

HEARING-AIDS

The 'Medresco' hearing-aid, devised by the electro-acoustics committee of the Medical Research Council with the help of the Post Office research department, is to be issued in two forms—one with external magnetic receiver, and the other with insert crystal receiver. The aids are to be issued, serviced, and supplied with batteries, free; but they will remain Government property. Initially only a limited number of hospitals will take part in the scheme, which will, gradually be expanded. It is expected that by the end of this year there will be sufficient audiometers for the principal hospitals participating in the scheme. Patients will normally be examined only on reference by their family doctor. The number requiring aids is uncertain; but since in the early stages demand is certain to exceed supply, priority will have to be given to the very deaf and to those handicapped in their work.

Major repairs are to be undertaken by the manufacturing firms. Distribution centres will receive a supply of replacements; the patient with a defective aid which has to be sent away will have the receivers removed and attached to a replacement, which will be issued in exchange for the defective aid. Minor repairs will be undertaken by technicians on the spot.

MEDICAL AND SURGICAL APPLIANCES

For patients both inside and outside the hospital, medical and surgical appliances are to be prescribed through the hospital service. Subject to special arrangements for artificial limbs, wheel chairs, and hearing-aids, it will be for the practitioner in charge of the patient to prescribe the appliance he considers necessary. But though, for the control of materials, children's shoes such as 'Start-Rite' can be obtained only on medical certification, these are not regarded as appliances and will not be supplied under these arrangements.

Appliances will be obtained by hospitals under a system of central contracts arranged by the Ministry of Pensions; and where necessary the contractor should be asked to arrange for the attendance of a fitter. Appliances so provided will be of good workmanship, design, and quality, and made from materials of high quality. Any patient wanting an appliance more expensive must make his own arrangements and meet the whole cost, except in the case of artificial limbs and dentures; here, as with glasses, the patient may have more expensive types approved by the Minister on payment of the extra cost. Duplicate appliances will be supplied only where the patient would suffer undue hardship through a single appliance becoming unserviceable, and where the occasional or alternative use of two appliances is medically desirable.

For the supply of an artificial limb the surgeon in charge of the patient may prescribe the type of limb required; or alternatively he may leave the prescription to the Ministry of Pensions limb surgeon. Hospitals will always inform the Ministry of Pensions of any patient needing an artificial limb; and arrangements will then be made for the patient's transfer to a Ministry of Pensions hospital or for his attendance as an outpatient at a *limb-fitting centre*. If desired, non-urgent cases requiring amputation will be transferred for the operation to a Ministry of Pensions hospital. In all cases subsequent action for the supply, repair, and renewal of artificial limbs will be undertaken by this Ministry; and for these purposes patients should be advised to communicate with the chief regional officer of the Ministry of Pensions.

The Ministry of Pensions is also responsible for the issue, repair, and renewal of wheel chairs. Motor-propelled chairs will normally be provided for patients who: (1) have undergone amputation of both legs, at least one above the knee; (2) are paraplegic; (3) have totally or almost totally lost the use of the legs; or (4) are badly disabled and need a machine to obtain or retain employment. Hand-propelled chairs will normally be provided to patients who: (1) are entitled to a motor-propelled chair but are medically unfit to drive one or prefer a hand-propelled chair; (2) have undergone double amputation below the knee; (3) need a chair "waking state" in an anæsthetised female gorilla with an aberrant stimulus during some experiments on the motor cortex, and he left his hearers to visualise the response produced in his own central nervous system. Again, Davy found that stimulation of part of area 8 with 20 millisec. pulses caused such violent intestinal peristalsis that intussusception invariably occurred. Earlier experiments, in which the duration and frequency of stimulus had not been so well controlled, had such divergent effects on the activity of the gut that the results could not be interpreted. The same was true of experiments on the activity of the gastric mucosa in secreting hydrochloric acid and pepsin.

From all this evidence Professor Fulton urged that knowledge of the correct parameters of stimulation were essential for the interpretation of cortical activity. He went on to apply these considerable advances in the technique of experiments on the cerebrum to the results of stimulation of the cerebellum.

In considering localisation of function and of the representation of the body in the cerebellum, Professor Fulton dealt with its anatomy and then with the effects of ablation and stimulation. The generally accepted division of the cerebellum is that of Larsell. On the basis of this division, the lobulus simplex of the anterior lobe represents movement of the head on the trunk, the culmen of the arm, the lobulus centralis of the leg, and the lingula of the caudal region. Hence, the spider monkey, which has an active and prehensile tail, has an extraordinarily well-developed lingula, which is very small in man.

Isolated removal of the nodulus causes a disturbance of equilibration, as Dow found, and this experimental observation is supported by the clinical fact that mid-line cerebellar lesions cause a disorder of balance without a commensurate disturbance of movement of the limb. Furthermore, medulloblastomas, which originate in the nodulus in children, are often present with a disorder of equilibration. Bard found that, whereas removal of parts or all of the cerebral hemispheres had no effect on motion sickness in dogs and monkeys, it was impossible to produce any disturbance in these animals after extirpation of the nodulus of the cerebellum.

It is difficult to remove the anterior lobe of the cerebellum, but if this is achieved there are grossly exaggerated supporting reactions which when studied alone are hard to interpret. When motor disorder is produced by experimental removal of the motor and premotor cortex in dogs, with a resulting hemiplegia, the effect of local removal of part of the anterior lobe of the cerebellum becomes more obvious; and, as Adrian has shown, there is clearly a close relationship between areas of the motor cortex and of the anterior cerebellar lobe.

If individual muscles are made to contract by stimuli applied to the motor cortex, and if the same procedures are carried out with simultaneous stimulation of special areas in the anterior lobe of the cerebellum, the resulting muscular contractions can be inhibited. But the importance of accurately controlling the *form of stimulus* is illustrated by the finding that, with different rates and durations of stimuli, facilitation and not inhibition will occur. Furthermore, some parts of the cerebellum are mainly concerned with inhibition and others with facilitation of movements which have been induced by cortical stimulation. Destruction of the dentate nucleus abolishes all inhibitory activity, and destruction of the fastigial nucleus abolishes all facilitation, when the appropriate areas of the cerebellum are stimulated.

Experiments of this kind show that there is accurate representation of the body in the anterior lobe of the cerebellum. The body in fact is represented spread-eagled, head downwards. The limbs are represented laterally, the digits being farthest out. The anterior lobe is concerned with posture, the body being accurately represented in it; the posterior lobe is concerned with the phasic relations of muscles; and the nodulus is responsible for equilibration. The cerebellar mechanism seems to be integrated with that of the cerebral cortex by causing inhibition or facilitation of muscular contraction as the needs of the moment demand, and there is now some experimental evidence as to how this is brought about.

THE BEWILDERED REBEL

To describe the delinquent as a "rebel against authority," Dr. Iago Galdston remarks,[1] is to introduce a corrupting fiction; for it suggests that on one side stands authority, and on the other a youth who will not accept or yield to that authority. But suppose the boy sees authority as a dangerous enemy? Or suppose he wishes to yield to authority but cannot? Is he still a rebel? The phrase, which Dr. Galdston quotes from New York County Lawyers Association's "statement of purpose," is partly redeemed by a *further concept* of the juvenile delinquent as sick rather than guilty. But to this he adds the query: "'Sick, how, as with typhoid or as with rickets?' For this makes all the difference possible." In one case the *patient* is attacked by a bacillus, in the other he is deprived of a need. If we ask "what *makes* the criminal?" we are shuffling off the blame, saying "there but for the grace of God go I;" and that, in Dr. Galdston's view, is a pharisaical and blasphemous remark—"as if it were all up to God, or to Fate, or to what you will, but not including us!"

Man is born, he reminds us, a grossly asocial animal, ridden hard and fast by his primitive instinctual drives; but carrying too the competence to love and the ability to learn by experience. The competence to love, in which all altruism is rooted, can only be realised in experience, however; and for too many people the chance is wanting. What experience they get inhibits rather than advances their social development. "Neither neurotic nor criminal behavior is individually or socially effective, and at the root of both failures lies the unrealised potentialities to love." Delinquency, then, is a deficiency disease, and the treatment is to alter the cultural atmosphere of our civilisation so that it allows the individual to realise his capacity for love and altruism.' Specifically this could be done, he thinks, by creating colonies for confirmed criminals, in which, though segregated, they could lead productive lives, as near to normal as possible; by getting rid of reformatories by degrees, and placing juvenile delinquents in specially selected foster homes; by training a large body of psychiatrically informed teachers, nursery-school supervisors, nurses, and social workers to keep guard over the young; and by providing plenty of child-guidance centres.

THE SUPERANNUATION OPTION

IN a leading article last week we drew attention to what we regarded as a fault in the arrangements by which practitioners holding suitable life-assurance policies may opt out of the National Health Service superannuation scheme. The condition whose effect would in some cases, we thought, be unfair was that the doctor would not have this option if his policy had been assigned to any other person. We are glad therefore to learn from the British Medical Association that, where the policy has been assigned for the purpose of a loan on the purchase of a practice, the Ministry of Health has agreed to waive this condition, provided the practitioner undertakes (1) to render the policy free from assignment as soon as possible and, in any case, when he receives his compensation under the Act for the loss of the right to sell his practice, and (2) not to assign the policy again.

[1] A Medical and Social Critique of Delinquency. Address delivered at the Colloquium on Juvenile Delinquency, March 20, 1948, under the auspices of the New York County Lawyers Association.

fractures in Theresienstadt and says that these are "related to sprue." Those who recovered from enteritis frequently developed œdema.

Apparently œdema was common. Like other workers in similar circumstances, Wolff-Eisner had difficulty in deciding which were simple cases of famine œdema and which were due to other causes, notably heart-failure. This might well have been important in Theresienstadt because many of the inmates were elderly. Many had a low blood-pressure and vasomotor instability.

VITAMIN DEFICIENCY

The classical diseases of vitamin deficiency do not seem to have been encountered, except possibly pellagra, which is said to have been "frequent" and to have improved under treatment with niacin; but there is no clear description from which the grounds for the diagnosis of pellagra may be judged. Scurvy is not mentioned, nor is there any clear indication of nutritional polyneuritis though the "spastic paretic" gait of many people walking about the camp is described; they trailed their feet, with frequent falls sometimes resulting in fractures of the femur. No indication of the type and frequency of anæmia is given, but two other doctors[3] interned in Theresienstadt have reported that it was usually orthochromic and was associated with several unusual clinical features. They attribute the anæmia to protein deficiency.

The mental consequences of underfeeding are well described—difficulty in remembering the names of colleagues and even important recent events. This is mentioned in apology for the shortcomings of the report; but the wonder is that Dr. Wolff-Eisner has been able to remember so much and describe it in terms that leave no doubt of its essential accuracy. The mode of death in starvation is also well described. The patient, weak but lucid, is talking at one moment, and then after a sudden effort, such as trying to get out of bed, is found to be dead.

INFECTIOUS DISEASES

The whole nutritional picture was complicated by the impact of various specific infectious diseases, as is usual in such circumstances.

In 1942 and 1943 a large epidemic of enteric fever swept through the camp. Clinically, it was like what the author had seen in the 1914–18 war, but an unusual feature was the frequency of recurrent attacks, often with a return of typical typhoid roseola; out of 80 of his cases, 5 were recurrences. The epidemic progressed although the majority of prisoners had been inoculated with T.A.B., and then it gradually died out despite the onset of hot weather and the constant influx of new unexposed prisoners. This was probably the result of energetic measures by the prisoners themselves to improve the hygiene of the camp. Survivors from the fever were often left with œdema or tuberculosis.
